  - Examples
    - IBM Blue Cloud
    - Amazon EC2
Definitions and layered view
Definition

“An IaaS cloud enables on-demand provisioning of computational resources in the forms of virtual machines (VMs) deployed in a cloud provider data centres (such as Amazon’s minimizing or even eliminating associated capital cost for cloud consumers ..”

Challenges
Figure 2. Cloud computing model for the future Internet of Services (IoS). Cloud technology enables the future IoS, and the infrastructure-as-a-service clouds represent this model’s foundation.
Examples of IaaS services

- Computing
- Storage
- Networking
- (Virtual) sensor/robot that can carry out given task(s)
Single IaaS providers

- Dynamic service provisioning
  - Dynamic mapping of services onto resources via environment (e.g. virtualization platform, software library) independent interfaces
    - Require advanced SOA interfaces
Single IaaS providers

- QoS and SLA negotiation
  - Require expressive mechanisms for QoS and SLA negotiation
    - Note: There are several negotiation mechanisms (e.g. offer / response. Offer/counter offer)
Single IaaS providers

- Service scalability
- Service elasticity
- Service monitoring, billing and payment
- Context / situation awareness
  - Geographic restrictions
    - Service deployed close to a group of users
    - Legal restrictions
Aggregating IaaS providers

- Service deployment across different providers
  - Hybrid clouds
  - Cloud brokering
    - Allow consumer to select most appropriate IaaS providers
      - Publication / discovery
Aggregating IaaS providers

- Interoperability
- Portability
Non functional challenges

- Security

- Availability, reliability and resilience

- Energy efficiency
Resource Management
Resource Management

- 1 - The problem
- 2 – VM migration (One of the techniques for tackling the problem)
- 3 - On VM Migration based algorithms for IaaS
Resource management problem

- On virtual machine life cycle
  - Determine expected resources needed at deployment
  - Configure VM
  - Decide where to place it
  - Start VM
  - Track resource usage
    - Hot spot: Inadequate resource to meet performance
    - Cold spot: Overprovisioned resources

Note: Resource usage pattern is highly dependent on applications types
Resource management problem

- Overall problem

“Minimized resource utilization while meeting IaaS users performance requirements”
Resource management problem

How could it be solved?

- Server consolidation
  - Avoid cold spots on physical machines
- Load balancing
  - Avoid discrepancy in resource usage on the different physical machines
- Hot spot mitigation
  - Avoid conditions where a VM does not have enough resource to meet the performance requirements
Resource management problem

- How could it be solved (Reference 4)?

**Figure 3.** Load balancing and consolidation scenarios.
Resource management problem

- How could it be solved?
  - Complementary / non mutually exclusive techniques
    - VM reconfiguration
      - Add / reduce resources
    - New VM instantiations
    - VM migration
On Virtual Machine Migration

- VM Migration
  - Process of transferring a VM with its state from one physical machine to another
    - Program transfer from one machine to another machine is not new, e.g.
      - Mobile agents (Late 90s, early 200s): Program than can start execution in a physical machine, suspend execution, then move to another machine to resume execution, then move again if necessary
On Virtual Machine Migration

- VM Migration

- Techniques

  - Suspend and copy
    - Suspend a VM execution, copy state (memory + processor), then resume execution on target machine
    - Downtime proportional to VM size and network bandwidth available for transfer
On Virtual Machine Migration

- VM Migration
  - Techniques
    - Live migration (Pre-copy and post-copy)
      - Minimize down time by either pre-copying or post-copying state
On Virtual Machine Migration

- VM Migration
  - Techniques
    - Live migration (Pre-copy) –
      - Pre-copy iteratively memory state to a set threshold (or until a condition is met) while still executing on host machine
      - Execution is suspended, processor state and remaining memory state are copied, and VM is restarted on target machine
On Virtual Machine Migration (Ref. 5)

**Stage 0: Pre-Migration**
- Active VM on Host A
- Alternate physical host may be preselected for migration
- Block devices mirrored and free resources maintained

**Stage 1: Reservation**
- Initialize a container on the target host

**Stage 2: Iterative Pre-copy**
- Enable shadow paging
- Copy dirty pages in successive rounds

**Stage 3: Stop and copy**
- Suspend VM on host A
- Generate ARP to redirect traffic to Host B
- Synchronize all remaining VM state to Host B

**Stage 4: Commitment**
- VM state on Host A is released

**Stage 5: Activation**
- VM starts on Host B
- Connects to local devices
- Resumes normal operation

**VM running normally on Host A**

**Overhead due to copying**

**Downtime (VM Out of Service)**

**VM running normally on Host B**
Virtual Machine Migration Based Algorithms

- Goals
  - Consolidation
  - Load balancing
  - Hot spot mitigation
Virtual Machine Migration Based Algorithms

- Questions
  - When to migrate?
  - Which VM to migrate?
  - Where to migrate the VM?
Virtual Machine Migration Based Algorithms

- Examples of constraints
  - Migration process overhead
  - Impact on applications
  - Degree of improvements in intended goals
Virtual Machine Migration Based Algorithms

- When to migrate?
  - Periodically, e.g.
    - data centres in several time zones
  - Hot spot
  - Excessive spare capacity
    - under-utilized VM migrated to free servers
    - VM migrated from overloaded servers
  - Load imbalance
  - Addition / removal of physical server
Virtual Machine Migration Based Algorithms

- Which VM to migrate?
  - overloaded VMs
  - Holistic approach
    - The overloaded VM is not always the best choice (Time for migrating it might be too high – A less overloaded VM might be considered)
  - Affinity based
    - If 2 VMs are communicating, it might not make sense to move one and let the other due to delays
Virtual Machine Migration Based Algorithms

- Where to migrate?
  - Available resource capacity
  - Affinity

Figure 1. The cloud ecosystem for building private clouds. (a) Cloud consumers need flexible infrastructure on demand. (b) Cloud management provides remote and secure interfaces for creating, controlling, and monitoring virtualized resources on an infrastructure-as-a-service cloud. (c) Virtual infrastructure (VI) management provides primitives to schedule and manage VMs across multiple physical hosts.
