ELEC 6131: Error Detecting and Correcting Codes

Instructor:

Dr. M. R. Soleymani, Office: EV-5.125, Telephone: 848-2424 ext: 4103. Time and Place: Tuesday, 17:45 – 20:15. Office Hours: Tuesday, 15:00 – 17:00

LECTURE 7: Reed Solomon Codes

Reed Solomon (RS) Codes

- ▶ In the last lecture, we discussed binary BCH codes. Binary BCH codes can be generalized to non-binary codes. In a non-binary code, codewords consist of symbols which are each $m \ge 2$ bits long.
- In general, non-binary codes can be defined over any Galois Field GF(q) where q is either a prime or a power of a prime. However, for obvious reasons, people are most interested in codes defined over $GF(2^m)$.
- RS Codes are a sub-class of non-binary BCH Codes. For Reed-Solomon Codes, take some integer *m*. Then each symbol is *m* bits long. This means that symbols belong to {0,1, ..., 2^{m-1}}.
- An (n, k) RS code consists of n symbols each of which is m bits long and has k information symbols and n-k parity symbols.
- For an RS code over $GF(2^m)$ we have $n = 2^m 1$.
- ▶ *k* can be any value less than *n*.
- An (n, k) RS code has the minimum distance $d_{min} = n k + 1$.
- It can correct $t = \left\lfloor \frac{d_{min}-1}{2} \right\rfloor = \left\lfloor \frac{n-k}{2} \right\rfloor$

Reed Solomon (RS) Codes

- An (n, k) RS code over $GF(2^m)$ has codewords of length n symbols, i.e., n * m bits out of which k * m are information (or systematic) bits.
- ▶ For example, a (255,239) RS Code over GF(2⁸) has codewords each 255 bytes and each codeword has 239 bytes of information and (*n*-*k*) = 16 bytes of parity. Such a code can correct up to ¹⁶/₂ = 8 bytes of error.
- ▶ Note that here when we correct one symbol, we may have corrected 1,2,.., m bits. If we have a burst of errors, that is a lot of errors adjacent to one another, RS Codes can be very useful. An RS Code which can correct t error symbols can correct (t − 1)m bits long bursts.
- ▶ The generating polynomial of t error correcting RS Code is:

$$g(x) = (x + \alpha)(x + \alpha^2) \dots (x + \alpha^{2t})$$

$$= g_0 + g_1 x + g_2 x^2 + \dots + g_{2t-1} x^{2t-1} + x^{2t}$$

with $g_i \in GF(2^m)$ for $0 \le i \le 2t$.

► $\alpha, \alpha^2, ..., \alpha^{2t}$ are roots of $X^n + 1$, so g(x) divides $X^n + 1$. So, g(x) generates a $2^m - ry$ cyclic code of length *n* with 2*t* parity symbols.

Encoding of RS Codes

We can simply multiply the information polynomial u(x) by g(x). However, this may not result in a systematic code. To make the code systematic, we multiply u(x) by X^{n-k} to get X^{n-k}u(x) which we divide by g(x) to get:

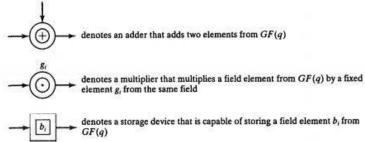

$$X^{n-k} u(x) = q(x)g(x) + b(x)$$

q(x)g(x) is a code polynomial. So we have:

$$v(x) = q(x)g(x) = x^{n-k}u(x) + b(x)$$

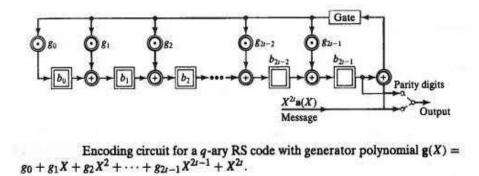

This means that we have u(x) as part of v(x), i.e., the code is systematic and b(x) is the parities polynomial.

The circuit on the next slide shows the encoding procedure. Too distinguish *m*-ary operation from binary, the following symbols are used.

Encoding of RS Codes

The following circuit shows the encoding procedure:

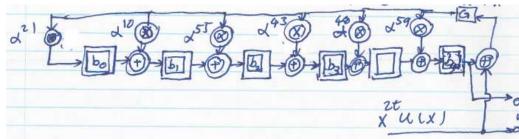

- 1) First, we close the gate and feed the information symbols into the division circuit. At the same time these information symbols are put on the line (to be transmitted): switch in lower position.
- 2) After feeding all *k* symbols, we open the gate (disconnect the feedback) and put switch in the up position, transmitting *2t* parity symbols.

Find the generating polynomial of triple error correcting code over $GF(2^6)$.

 $g(x)=(x+\alpha)(x+\alpha^2)(x+\alpha^3)(x+\alpha^4)(x+\alpha^5)(x+\alpha^6)$

 $= \alpha^{21} + \alpha^{10}x + \alpha^{55}x^2 + \alpha^{43}x^3 + \alpha^{48}x^4 + \alpha^{59}x^5 + x^6$

▶ The Parity-Check matrix of an RS code is given as:

$$H = \begin{bmatrix} 1 & \alpha & \alpha^2 & \cdots & \alpha^{n-1} \\ 1 & \alpha^2 & (\alpha^2)^2 & \cdots & (\alpha^2)^{n-1} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \alpha^{2t} & (\alpha^{2t})^2 & \cdots & (\alpha^{2t})^{n-1} \end{bmatrix}$$

- Decoding of RS Codes:
- 1) Find syndrome.
- 2) Find <u>error-locator</u> polynomial.
- 3) Find error-value evaluator.
- 4) Find the error locations and error values and correct.

Assume that the codeword $\underline{v} = (v_0, v_1, \dots, v_{n-1})$ is transmitted or equivalently

 $v(x) = v_0 + v_1 x + v_2 x^2 + \dots + v_{n-1} x^{n-1}$

Assume that r(x) is received:

 $r(x) = r_0 + r_1 x + r_2 x^2 + \dots + r_{n-1} x^{n-1}$

► r(x) = v(x) + e(x), where e(x) is the error polynomial $e(x) = r(x) + v(x) = e_0 + e_1x + \dots + e_{n-1}x^n$

- Assume we have errors at locations: $j_1, j_2, \dots, j_{\gamma}$
- Denote the values of error by $e_{j_1}, e_{j_2}, \dots, e_{j_{\gamma}}$, we have:

$$e_i = \begin{cases} 0 & i \neq j_1, \dots, j_{\gamma} \\ e_{j_e} \text{ if } i = j_e \epsilon \{j_1, \dots, j_e\} \end{cases}$$

So, we can write:

 $e(x) = e_{j_1} x^{j_1} + e_{j_2} x^{j_2} + \dots + e_{j_{\gamma}} x^{j_{\gamma}}$

- So, what we need to do is to find j_1, \dots, j_{γ} as well as $e_{j_1}, \dots, e_{j_{\gamma}}$.
- That is, we have 2γ unknowns.
- Remember that

$$v(\alpha^{i}) = 0 \qquad i = 1, 2, \dots, 2t$$

$$r(\alpha^{i}) = v(\alpha^{i}) + e(\alpha^{i}) = s_{i}$$

- So, $s_i = r(\alpha^i) = e(\alpha^i)$
- That is, we substitute α^i , i = 1, 2, ..., 2t in r(x) to get 2t syndromes. These provide 2t equations with j'_i 's and e_{j_i} 's as their components. In order to be able to solve for the 2γ unknowns, we need to have 2γ equations, i.e., $2t = 2\gamma \rightarrow t = \gamma$. That is a proof that RS Code can correct *t* errors.

Now let's expand
$$s_i = e(\alpha^i)'s$$
:

$$s_1 = e_{j_1}\alpha^{j_1} + e_{j_2}\alpha^{j_2} + \dots + e_{j_{\gamma}}\alpha^{j_{\gamma}}$$

$$s_2 = e_{j_1}\alpha^{2j_1} + e_{j_2}\alpha^{2j_2} + \dots + e_{j_{\gamma}}\alpha^{2j_{\gamma}}$$

$$\vdots$$

$$s_{2t} = e_{j_1}\alpha^{2tj_1} + e_{j_2}\alpha^{2tj_2} + \dots + e_{j_{\gamma}}\alpha^{2tj_{\gamma}}$$

$$\text{Let } \beta_i \triangleq \alpha^{j_i} \text{ and } \delta_i \triangleq e_{j_i}, \text{ for } 1 \le i \le \gamma. \text{ Then:}$$

$$s_1 = \delta_1\beta_1 + \delta_2\beta_2 + \dots + \delta_{\gamma}\beta_{\gamma}$$

$$s_2 = \delta_1\beta_1^2 + \delta_2\beta_2^2 + \dots + \delta_{\gamma}\beta_{\gamma}^2$$

$$\vdots \\ s_{2t} = \delta_1 \beta_1^{2t} + \delta_2 \beta_2^{2t} + \dots + \delta_\gamma \beta_\gamma^{2t}$$

• Define the error locator polynomial:

$$\sigma(x) = (1 + \beta_1 x)(1 + \beta_2 x) \dots (1 + \beta_\gamma x)$$
$$= \sigma_0 + \sigma_1 x + \sigma_2 x^2 + \dots + \sigma_\gamma x^\gamma$$

We can see that:

$$\sigma_0 = 1$$

$$\sigma_1 = \beta_1 + \beta_2 + \dots + \beta_{\gamma} = s_1$$

$$\sigma_2 = \beta_1 \beta_2 + \dots + \beta_{\gamma-1} \beta_{\gamma} = \sigma_1 s_1 + s_2$$

.

▶ Overall, we get the following equations named Newton equalities:

$$s_{\gamma+1} + \sigma_1 s_{\gamma} + \sigma_2 s_{\gamma-1} + \dots + \sigma_{\gamma} s_1 = 0$$

$$s_{\gamma+2} + \sigma_1 s_{\gamma+1} + \sigma_2 s_{\gamma} + \dots + \sigma_{\gamma} s_2 = 0$$

$$\vdots$$

$$s_{2t} + \sigma_1 s_{2t-1} + \sigma_2 s_{2t-2} + \dots + \sigma_{\gamma} s_{2t-\gamma} = 0$$

See slide 27 for proof.

- The same as BCH Codes, we start from $\sigma(x)=1$ in stage 0 say we call it $\sigma^{(0)}(x)$ and try to increase the number of terms so that all equations are satisfied.
- Assume that at stage μ we have:

$$\sigma^{(\mu)}(x) = \sigma_0^{(\mu)} + \sigma_1^{(\mu)}x + \dots + \sigma_{L_{\mu}}^{(\mu)}x^{l_{\mu}}$$

This means that we have coefficients $\sigma_0^{(\mu)}, \sigma_1^{(\mu)}, \dots, \sigma_{L_{\mu}}^{(\mu)}$ of a polynomial that satisfies the first μ Newton equalities. We try to apply these coefficients to μ +1-st equality, i.e., form

$$S_{\mu+1} + \sigma_1^{(\mu)} S_{\mu} + \dots + \sigma_{L_{\mu}}^{(\mu)} S_{\mu+1-l}$$

► If this gives us a zero it means that $\sigma_0^{(\mu)}, \sigma_1^{(\mu)}, ... + \sigma_{L_{\mu}}^{(\mu)}$ satisfy μ +1-st equality, otherwise we have to modify the polynomial.

So, find the discrepancy:

$$d_{\mu} = S_{\mu+1} + \sigma_1^{(\mu)} S_{\mu} + \sigma_2^{(\mu)} S_{\mu-1} + \dots + \sigma_{L\mu}^{(\mu)} S_{\mu+1-L}$$

• If the discrepancy $d_{\mu} = 0$ then:

$$\sigma^{(\mu+1)}(x) = \sigma^{(\mu)}(x)$$

and continue. Otherwise:

$$\sigma^{(\mu+1)}(x) = \sigma^{(\mu)}(x) + d_{\mu}d_{\rho}^{-1}x^{\mu-\rho}\sigma^{(\rho)}(x)$$

where ρ is the stage closest to μ such that $d_{\rho} \neq 0$ and $\rho - l_{\rho}$ has the largest value. Then:

$$l_{\mu} = \max(l_{\mu}, l_{\rho} + \mu - \rho)$$

• Continue this iteration until we get to stage 2*t* then:

$$\sigma(x) = \sigma^{(2t)}(x)$$

Initialization: start by filling out the first two rows:

Consider triple-error correcting code over $GF(2^4)$. Let $r(x) = \alpha^7 x^3 + \alpha^3 x^6 + \alpha^4 x^{12}$

Then:

$$g(x) = (x + \alpha)(x + \alpha^{2})(x + \alpha^{3})(x + \alpha^{4})(x + \alpha^{5})(x + \alpha^{6})$$

$$= \alpha^{6} + \alpha^{9}x + \alpha^{6}x^{2} + \alpha^{4}x^{3} + \alpha^{14}x^{4} + \alpha^{10}x^{5} + x^{6}$$

$$s_{1} = r(\alpha) = \alpha^{10} + \alpha^{9} + \alpha = \alpha^{12}$$

$$s_{2} = r(\alpha^{2}) = \alpha^{13} + 1 + \alpha^{13} = 1$$

$$s_{3} = r(\alpha^{3}) = \alpha + \alpha^{6} + \alpha^{10} = \alpha^{14}$$

$$s_{4} = r(\alpha^{4}) = \alpha^{4} + \alpha^{12} + \alpha^{7} = \alpha^{10}$$

$$s_{5} = r(\alpha^{5}) = \alpha^{7} + \alpha^{3} + \alpha^{4} = 0$$

$$s_{6} = r(\alpha^{6}) = \alpha^{10} + \alpha^{9} + \alpha = \alpha^{12}$$

TABLE 7.2: Steps for finding the error-location polynomial of the (15,9) RS code over GF(24).

#	$\sigma^{(\mu)}(X)$	d _p	I _µ	$\mu - l_{\mu}$
-1	1	1	0	-1
0	1	a12	0	0
1	$1 + \alpha^{12} X$	α^7	1	$0(\text{take } \rho = -1)$
2	$1 + \alpha^3 X$	1	1	$1(\text{take } \rho = 0)$
3	$1 + \alpha^3 X + \alpha^3 X^2$	a7	2	$1(\text{take } \rho = 0)$
4	$1 + \alpha^4 X + \alpha^{12} X^2$	a10	2	$2(\text{take } \rho = 2)$
5	$1 + \alpha^7 X + \alpha^4 X^2 + \alpha^6 X^3$	0	3	$2(take \rho = 3)$
	$1 + \alpha^7 X + \alpha^4 X^2 + \alpha^6 X^3$	-	-	10 Table 200 Salar

- Step 2. To find the error-location polynomial $\sigma(X)$, we fill out Table 7.1 and
- Step 3. By substituting 1, $\alpha, \alpha^2, \dots, \alpha^{14}$ into $\sigma(X)$, we find that α^3, α^9 , and α^{12} are roots of $\sigma(X)$. The reciprocals of these roots are α^{12}, α^6 , and α^3 , which are the error-location numbers of the error pattern $\mathbf{e}(X)$. Thus, errors occur at positions X3, X6, and X12.

Decoding of RS Codes: Vicker's Formulation

- A more straightforward algorithm where the correction term is evolved as the iterations go ahead is given in Vicker's text. The algorithm is as follows:
- 1) Compute syndromes $S_1 = S_{2t}$.
- 2) Initialize the algorithm by letting $\mu=0$, $\sigma^{(0)}(x) = 1$, l = 0 and T(x) = x
- 3) Set $\mu = \mu + 1$ and compute discrepancy d_{μ} ,

$$d_{\mu} = S_{\mu} + \sum_{i=1}^{l} \sigma_i^{(\mu-1)} S_{\mu-i}$$

4) If d_μ = 0 then go to 8.
5) Modify the polynomial as:

$$\sigma^{(\mu)}(x) = \sigma^{(\mu-1)}(x) + d_{\mu}T(x)$$

Decoding of RS Codes: Vicker's Formulation

6) If $2l \ge \mu$ then go to step 8.

- 7) Set $l = \mu l$ and $T(x) = d_{\mu}^{-1} \sigma^{(\mu-1)}(x)$.
- 8) Set T(x) = x.T(x).
- 9) If $\mu < 2t$ go to step 3.

10) Determine $\sigma(x) = \sigma^{(2t)}(x)$. If the roots are distinct and in the right field, then determine the error values, correct the errors and STOP.

11) Declare a decoding failure and STOP.

▶ In the next slide, we do the previous example again using Vicker's notation.

Decoding of RS Codes: Vicker's Formulation

▶ Form the table with the following syndromes:

$$s_1 = \alpha^{12}, s_2 = 1, s_3 = \alpha^{14}, s_5 = 0$$
, $s_6 = \alpha^{12}$

This table shows the formation of error locator polynomial:

$$\sigma(x) = 1 + \alpha^7 x + \alpha^4 x^2 + \alpha^6 x^3$$

μ	Sμ	$\sigma^{(\mu)}(x)$	$d^{(\mu)}$	L_{μ}	T(x)
0	-	1	-	0	x
1	α^{12}	$1 + \alpha^{12}x$	α^{12}	1	$\alpha^3 x$
*2	1	$1 + \alpha^3 x$	α^7	1	$\alpha^8 x + \alpha^5 x^2$
**3	α^{14}	$1 + \alpha^{13}x + \alpha^5x^2$	1	2	$x + \alpha^3 x^2$
4	α^{10}	$1 + \alpha^4 x + \alpha^{12} x^2$	α^{11}	2	$\alpha^4 x + \alpha^2 x^2 + \alpha^9 x^3$
5	0	$1 + \alpha^9 x + \alpha^4 x^3$	α^{10}	3	$\alpha^5 x + \alpha^9 x^2 + \alpha^3 x^3$
6	α^{12}	$1 + \alpha^7 x + \alpha^4 x^2 + \alpha^6 x^3$	α^{10}	3	

* $d_1 = s_2 + \sigma_1 s_1 = 1 + \alpha^{12} \cdot \alpha^{12} = \alpha^9 + 1 = \alpha^7$ ** $d_2 = s_3 + \sigma_1 s_2 = 1 + \alpha^{14} + \alpha^3 \cdot 1 = 1$

- Consider (7,3) RS Code over GF(8) with $r(x) = \alpha^2 x^6 + \alpha^2 x^4 + x^3 + \alpha^5 x^2$.
- Although we have done the generation of g(x) and encoding, let's start from ground zero for doing some exercise in Galois field arithmetic. Let's start with $p(x)=x^3+x+1$. Take α to be a primitive element of this field, i.e., $\rho(x)$. That is $\alpha^3 + \alpha + 1 = 0$ or $\alpha^3 = \alpha+1$.

0	0	0	0	0
1	1	0	0	1
α1	0	1	0	α
$\alpha^2 = \alpha. \alpha$	0	0	1	α^2
$\alpha^3 = \alpha^2. \alpha$	1	1	0	α+1
$lpha^4$	0	1	1	$\alpha^2 + \alpha$
α^5	1	1	1	$\alpha^2 + \alpha + 1$
α^{6}	1	0	1	$\alpha^2 + 1$
α^7	1	0	0	1

Note:

 $\alpha^{3} = \alpha^{2} \cdot \alpha = \alpha + 1$ $\alpha^{4} = \alpha \cdot \alpha^{3} = \alpha(\alpha + 1) = \alpha^{2} + \alpha$ $\alpha^{5} = \alpha^{4} \cdot \alpha = (\alpha^{2} + \alpha)\alpha = \alpha^{3} + \alpha^{2} = \alpha^{2} + \alpha + 1$ $\alpha^{6} = \alpha (\alpha^{2} + \alpha + 1) = \alpha^{2} + 1$ $\alpha^{7} = \alpha (\alpha^{2} + 1) = \alpha^{3} + \alpha = \alpha + 1 + \alpha = 1$

Now, g(x) is:

$$g(x) = (x + \alpha)(x + \alpha^{2})(x + \alpha^{3})(x + \alpha^{4})$$

= $[x^{2} + (\alpha + \alpha^{2})x + \alpha^{3}][x^{2} + (\alpha^{3} + \alpha^{4})x + \alpha^{7}]$
= $[x^{2} + \alpha^{4}x + \alpha^{3}][x^{2} + \alpha^{6}x + 1]$
= $x^{4} + \alpha^{3}x^{3} + x^{2} + \alpha x + \alpha^{3}$

Computing Syndromes:

$$S_i = r(\alpha^i).$$
 $i = 1,2,3,4$

In this case, since the number of parities are less than the number of information symbols, it is reasonable to use r(αⁱ) = S_i. However, for high rate codes where n − k ≪ k, it is better to divide r(x) by g(x) to get

$$r(x) = g(x) q(x) + b(x)$$

Where b(x) is a polynomial of degree less than or equal *n*-*k*.

$$S_i = r(\alpha^i) = g(\alpha^i)q(\alpha^i) + b(\alpha^i) \qquad i = 1, 2, ..., 2t.$$

Since $g(\alpha^i) = 0 \qquad i = 1, ..., 2t,$
 $S_i = b(\alpha^i)$

$$s_{2} = b(\alpha^{2}) = \alpha^{9} + \alpha^{12} + \alpha^{10} + \alpha^{3} = \alpha^{3}$$

$$s_{3} = b(\alpha^{3}) = \alpha^{13} + \alpha^{15} + \alpha^{12} + \alpha^{4} = \alpha^{4}$$

$$s_{4} = b(\alpha^{4}) = \alpha^{17} + \alpha^{18} + \alpha^{14} + \alpha^{5} = \alpha^{3}$$

• Using Berlekamp's algorithm, we find $\sigma(x) = 1 + \alpha^2 x + \alpha x^2$

μ	Sμ	$\sigma^{(\mu)}(x)$	d_{μ}	L	T(x)
0	-	1	-	0	Х
1	α^6	$1 + \alpha^6 x$	α^6	1	αx^*
2	α^3	$1 + \alpha^4 x$	α^2	1	$\alpha x^{2^{**}}$
3	α^4	$1 + \alpha^4 x + \alpha^6 x^2$	α^5	2	$\alpha^2 x + \alpha^6 x^2$
4	α^3	$1 + \alpha^2 x + \alpha x^2$	α ⁶	-	-

Notes:

For
$$\mu=1$$
 L=0 $\rightarrow 2L < \mu \rightarrow L = \mu - L = 1$ and

$$T(x) = \frac{\sigma^{(0)}(x)}{d_1} = \frac{x}{\alpha^6} = \alpha x.$$

For $\mu=2$

$$d_{\mu} = s_{\mu} + \sum_{i=1}^{L} \sigma_i^{(\mu-1)} s_{\mu-i} \to \mu_2 = s_2 + \sigma_1^{(1)} S_1$$

Or

$$\mu_2 = \alpha^3 + \alpha^6 \cdot \alpha^6 = \alpha^3 + \alpha^5 = \alpha^2$$

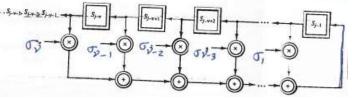

$$2L = 2 \ge \mu = 2 \rightarrow T(x) = xT(x) \rightarrow T(x) = \alpha x^2$$

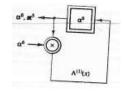

- The Massy Algorithm is based on Linear Feedback Shift Register (LFSR) synthesis technique.
- Note that for γ errors, we have the following Newton equalities.

$$s_j = \sigma_1 s_{j-1} + \sigma_2 s_{j-2} + \dots + \sigma_\gamma s_{j-\gamma}$$

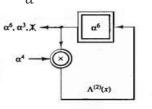

This relationship can be represented as LFSR circuit looking like:

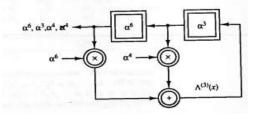

- The problem of finding error-locator polynomial is then to find an LFSR of minimal length such that the first 2t elements in the output sequence are $s_1, s_2, ..., s_{2t}$.
- The coefficients of the filter are then the coefficient of $\sigma(x)$.
- ► For the above (7,3) RS code, we start with:

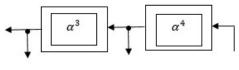

- This works for the $s_1 = \alpha^6$ as it outputs the content of the register ,i.e., α^6 . But after the application of the seconds clock, the output will be α^6 . $\alpha^6 = \alpha^{12} = \alpha^5$ which is not $s_{2=}\alpha^3$.
- To correct the situation, we change the filter tap to α^4 which is $\frac{\alpha^6}{\alpha^2}$ and therefore, the output after the clocking will be $\frac{\alpha^5}{\alpha^2} = \alpha^3 = s_2$.

- After the next clock the output will be α^3 . $\alpha^4 = 1$ which is not equal to $s_3 = \alpha^4$.
- To correct this we need to add α^5 so that, we get $1 + \alpha^5 = \alpha^4 = s_3$. We keep the above and add a stage with α^6 in the register and α^6 as the tap.

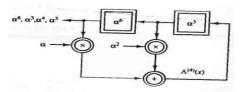

- This circuit outputs α^6 first and then calculates α^6 . $\alpha^6 + \alpha^3$. $\alpha^4 = \alpha^5 + 1 = \alpha^4$
- Content of the rightmost SR is moved to left and α^4 is loaded into it.

- So, the next output is $\alpha^3 = s_2$.
- Next $\alpha^3 \cdot \alpha^6 + \alpha^4 \cdot \alpha^4 = \alpha^2 + \alpha = \alpha^4$ is placed in right register and α^4 is moved left:

- Now α^4 is output which is s_3 . But the next output is $\alpha^4 \neq s_4 = \alpha^3$
- ▶ To correct this, we modify the taps of the LFSR to:

► It is easy to see that this circuit outputs α^6 , α^3 , α^4 , α^3 , *i.e.* s_1 , s_2 , s_3 , s_4

- We have found the error-locator polynomial $\sigma(X)$. We can solve it, using Chien Search, to find the error locations $\beta_i = \alpha^{j_i}$ i=1,2, ..., γ .
- Now we need to find $\delta_i = e_{j_i}$, i.e., error values at the error locations and correct them, That is the equations are:

$$S_1 = e_{j_1} \alpha^{j_1} + e_{j_2} \alpha^{j_2} + \dots + e_{j_{\gamma}} \alpha^{j_{\gamma}}$$

$$S_{2t} = e_{j_1} \alpha^{2tj_1} + e_{j_2} \alpha^{2tj_2} + \dots + e_{j_\gamma} \alpha^{2tj_\gamma}$$

With $\alpha^{j_i's}$ and S_i 's known. Or equivalently:

$$S_{1} = \delta_{1}\beta_{1} + \delta_{2}\beta_{2} + \dots + \delta_{\gamma}\beta_{\gamma}$$
$$S_{2} = \delta_{1}\beta_{1}^{2} + \delta_{2}\beta_{2}^{2} + \dots + \delta_{\gamma}\beta_{\gamma}^{2}$$
$$\vdots$$
$$S_{2t} = \delta_{1}\beta_{1}^{2t} + \delta_{2}\beta_{2}^{2t} + \dots + \delta_{\gamma}\beta_{\gamma}^{2t}$$

• Let's define the syndrome polynomial:

$$S(x) = S_1 + S_2 X + \dots + S_{2t} X^{2t} + S_{2t+1} X^{2t} + \dots$$
$$= \sum_{j=1}^{\infty} S_j X^{j-1}$$

Note that S(x) has an infinite number of terms whose first 2t terms are known:

$$S_j = \sum_{l=1}^{\gamma} \delta_l \beta_l^j \qquad j = 1, 2, \dots, 2t$$

Substituting these (but now for all terms), we get:

$$\begin{split} S(x) &= \sum_{j=1}^{\infty} x^{j-1} \sum_{l=1}^{\gamma} \delta_l \beta_l^j \\ &= \sum_{l=1}^{\gamma} \delta_l \beta_l \sum_{j=1}^{\infty} (\beta_l x)^{j-1} \end{split}$$

But

$$\sum_{j=1}^{\infty} (\beta_l x)^{j-1} = \frac{1}{1 + \beta_l x}$$

Substituting
$$\sum_{j=1}^{\infty} (\beta_l x)^{j-1} = \frac{1}{1+\beta_l x}$$
, we get:
$$S(x) = \sum_{l=1}^{\gamma} \frac{\delta_l \beta_l}{1+\beta_l x}$$

• Multiplying $\sigma(x) = \prod_{i=1}^{\gamma} (1 + \beta_i x)$ and S(x), we get:

$$S(x)\sigma(x) = \sum_{l=1}^{\gamma} \delta_l \beta_l \prod_{i=1. \ i \neq l}^{\gamma} (1 + \beta_i x) \triangleq Z_0(x)$$

• We can also write:

$$\begin{aligned} \sigma(x)S(x) &= \left[1 + \sigma_1 x + \dots + \sigma_{\gamma} x^{\gamma}\right] [S_1 + S_2 x + S_3 x^2 + \dots] \\ &= S_1 + (S_2 + \sigma_1 S_1) x + (S_3 + \sigma_1 S_2 + \sigma_2 S_1) x^2 + \dots \\ &\dots + \left(\sigma_{2t} + \sigma_1 S_{2t-1} + \dots + \sigma_{\gamma} S_{2t-\gamma}\right) x^{2t-1} + \dots \end{aligned}$$

So:

$$Z_0(x) = S_1 + (S_2 + \sigma_1 S_1)x + (S_3 + \sigma_1 S_2 + \sigma_2 S_1)x^2 + \cdots + (S_{\gamma} + \sigma_1 S_{\gamma-1} + \cdots + \sigma_{\gamma-1} S_1)x^{\gamma-1}$$

• Let's substitute
$$\beta_k^{-1}$$
 in $Z_0(x)$:

$$Z_0(\beta_k^{-1}) = \sum_{l=1}^{\gamma} \delta_l \beta_l \prod_{\substack{i=1, i \neq l}}^{\gamma} (1 + \beta_i \beta_k^{-1})$$
$$= \delta_k \beta_k \prod_{\substack{i=1, i \neq k}}^{\gamma} (1 + \beta_i \beta_k^{-1})$$

• Taking derivative of $\sigma(x)$:

$$\sigma'(x) = \frac{d}{dx} \prod_{i=1}^{\gamma} (1 + \beta_i x) = \sum_{l=1}^{\gamma} \beta_l \prod_{i=1, i \neq l}^{\gamma} (1 + \beta_i x)$$

Then

$$\sigma'(\beta_k^{-1}) = \beta_k \prod_{i=1, i \neq k}^{\gamma} (1 + \beta_i \beta_k^{-1})$$

► So,

$$\delta_k = \frac{Z_0(\beta_k^{-1})}{\sigma'(\beta_k^{-1})}$$

• Let's $[\sigma(x)S(x)]_{2t}$ represent the first 2t terms of $\sigma(x)S(x)$. Then

 $\sigma(x)S(x)-[\sigma(x)S(x)]_{2t}$

is divisible by X^{2t} .

► That is:

But,

 $[\sigma(x)S(x)]_{2t} = Z_0(x)$

 $\sigma(x)S(x) \equiv [\sigma(x)S(x)]_{2t} mod X^{2t}$

and we have:

$$\sigma(x)S(x) \equiv Z_0(x)modx^{2t}$$

▶ This is called the <u>key equation</u> that has to be solved in decoding of RS codes.

• Consider the (7, 3) code in the previous example:

We had
$$S_1 = \alpha^6$$
, $S_2 = \alpha^3$, $S_3 = \alpha^4$ and $S_4 = \alpha^3$,

So:

$$S(x) = \alpha^6 + \alpha^3 x + \alpha^4 x^2 + \alpha^3 x^3$$

▶ We also found:

$$\sigma(x) = 1 + \alpha^2 x + \alpha x^2 \rightarrow \sigma'(x) = \alpha^2 + 2\alpha x = \alpha^2$$

So:

$$Z_0(x) = \sigma(x)S(x)modx^4 = (1 + \alpha^2 x + \alpha x^2)(\alpha^6 + \alpha^3 x + \alpha^4 x^2 + \alpha^3 x^3)$$

= $\alpha^6 + x$

We can find the error locations by solving σ(x)=0 to get β₁ = α³ and β₂ = α⁵
So,

$$e_3 = \delta_1 = \frac{Z_0(\alpha^{-3})}{\sigma'(\alpha^{-3})} = \frac{\alpha^6 + (\alpha^{-3})}{\alpha^2} = \alpha^4 + \alpha^2 = \alpha$$

and

$$e_5 = \delta_2 = \frac{z_0(\alpha^{-5})}{\sigma'(\alpha^{-5})} = \frac{\alpha^6 + \alpha^{-5}}{\alpha^2} = \alpha^4 + 1 = \alpha^5$$

 $e(X) = \alpha X^3 + \alpha^5 X^5$

► So,

Decoding of RS Codes: Another Example

- Consider the (15, 9) code we considered before.
- The syndromes are: $s_1 = \alpha^{12}$, $s_2 = 1$, $s_3 = \alpha^{14}$, $s_4 = \alpha^{10}$, $s_5 = 0$ and $s_6 = \alpha^{12}$ We found that $\sigma(x) = 1 + \alpha^7 x + \alpha^4 x^2 + \alpha^6 x^3$.
- Letting $x = \alpha^3$, we get $\sigma(\alpha^3) = 0$. So, the roots of $\sigma(x)$ are α^3 , α^6 and α^{12} .
- Therefore, errors are at locations x^3 , x^6 and x^{12} .
- Now, we form the error-value evaluator function:

$$Z_0(x) = s_1 + (s_2 + \sigma_1 s_1)x + (s_3 + \sigma_1 s_2 + \sigma_2 s_1)x^2$$

= $\alpha^{12} + (1 + \alpha^7 \alpha^{12})x + (\alpha^{14} + \alpha^7 + \alpha^4 \alpha^{12})x^2$
= $\alpha^{12} + (1 + \alpha^4)x + (\alpha^{14} + \alpha^7 + \alpha)x^2 = \alpha^{12} + \alpha x$

The error values are

$$e_{3} = \frac{Z_{0}(\alpha^{-3})}{\sigma'(\alpha^{-3})} = \frac{\alpha^{12} + \alpha \alpha^{-3}}{\alpha^{3}(1 + \alpha^{6} \alpha^{-3})(1 + \alpha^{12} \alpha^{-3})} = \frac{\alpha}{\alpha^{9}} = \alpha^{7}$$

$$e_{6} = \frac{Z_{0}(\alpha^{-6})}{\sigma'(\alpha^{-6})} = \frac{\alpha^{12} + \alpha \alpha^{-6}}{\alpha^{6}(1 + \alpha^{3} \alpha^{-6})(1 + \alpha^{12} \alpha^{-6})} = \frac{\alpha^{3}}{1} = \alpha^{3}$$

$$e_{12} = \frac{Z_{0}(\alpha^{-1})}{\sigma'(\alpha^{-12})} = \frac{\alpha^{12} + \alpha \alpha^{-12}}{\alpha^{12}(1 + \alpha^{3} \alpha^{-12})(1 + \alpha^{6} \alpha^{-12})} = \frac{\alpha^{6}}{\alpha^{2}} = \alpha^{4}$$

So, the error pattern is:

$$e(x) = \alpha^7 x^3 + \alpha^3 x^6 + \alpha^4 x^{12}$$
