Proxy Lists or
Lists of Proxies

Domain Problem

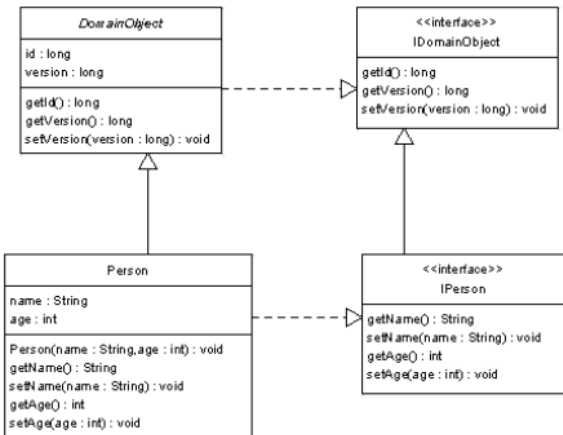

- ▶ We need to reduce representational gap
- ▶ We need to represent identity
- ▶ We need to represent a temporal identity
- ▶ We need to do this simply in a way that can reflect persisted data
- ▶ It may help to think of these as responsibilities that we have always had, we are just now specifically addressing them.

Domain Object

- ▶ We have already used Domain Object as a term, let's formalize it
- ▶ It represents necessary identity
- ▶ It isolates our data along conceptual boundaries
- ▶ It is easy to map to persisted storage using our existing patterns

Domain Object UML

- ▶ Why not treat it as Layer Supertype?

Domain Object Alternatives

- ▶ In SOENEA we support different id types besides long
- ▶ ... this includes compound ids. Is that a good idea?
- ▶ Does every Domain Object need a version?
- ▶ Could we move some of the responsibility of interacting with UoW into Domain Objects?

New Patterns, Old Responsibilities

Domain Objects

Front Controllers, Dispatchers and Commands

Proxy Lists or Lists of Proxies

New Patterns,
Old
Responsibilities
Domain Objects
**Front Controllers,
Dispatchers and
Commands**
Proxy Lists or
Lists of Proxies

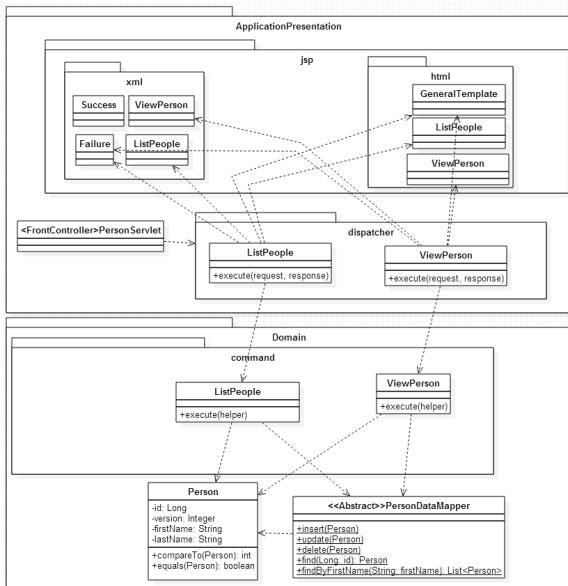

The Problem With Front Commands

- ▶ What Layer are Front Commands in?
- ▶ What do they do?

Dispatchers

- ▶ Commands can be in the domain layer if they are strictly domain logic
- ▶ Split out interaction with views
- ▶ Dispatchers then Dispatch to Commands and to Views
- ▶ Dispatchers read like high-level use cases
- ▶ Commands read like low-level use cases

Dispatcher UML

**Proxy Lists or
Lists of Proxies**

Lots of Lists

- ▶ Warning: Over the years, I've become less fond of this approach. But...
- ▶ Sometimes your classes have fields that are lists of other things
- ▶ Really, this probably applies to any collection (Lists, Sets, Maps, Heaps)
- ▶ We have seen proxies as a means to load less data
- ▶ Can we use proxies for the same thing here?

Lists of Proxies

- ▶ What if instead of loading up each Domain Object we loaded up a list of their ids
- ▶ We could then populate a list with proxies
- ▶ Proxies only loaded as needed
- ▶ Table with this list of ids is often a separate table anyway
- ▶ Is this a good enough reason?

Proxy Lists

- ▶ What if the whole list was a proxy?
- ▶ What if it knew the parent id, and type of thing wanted
- ▶ Effectively, it knows which find method to call and has a Domain Object to pass in
- ▶ Database call gets all rows at once, only when needed
- ▶ Does this sound like it works?

Hint about a solution we'll see later

- ▶ These solutions still try to hold these lists as structurally relevant
- ▶ Maybe they are!
- ▶ But maybe they're just needed in certain cases. . . behaviourally relevant
- ▶ Then we can skip proxies like this altogether
