# Introduction

- Digital systems continuously grow in scale and functionality

Performance of integrated circuits (IC) doubling every year

Microprocessors containing 500M gates, doubling of frequency per generation, transistor scale by 30% per generation

Telecommunication chips are deep submicron application-specific integrated circuits (ASICs) with more than 1M gates

I/O pins limit observability and controllability, likelihood of design errors increasing

In 1994, problems with Intel Pentium and Pentium Pro microprocessors. Cost of correction about \$250 M

In 1995, problem with TI 320C32 floating point digital signal processor

Failure of Ariane 6 due to bad specification of SW module for reuse

- **Our goal: develop awareness of formal verification methods as complement to simulation to improve design quality.**
- *Formal Methods*: mathematically-based languages, techniques, and tools for specifying and verifying systems
- Increase understanding of a system by revealing *inconsistencies*, *ambiguities*, and *incompleteness*  
.... often even by just going through the process of rigorous specification...

# Terminology

**Formal Methods** is the application of logic to the development of “correct” systems

**Correctness** is classically viewed as two separate problems, **validation** and **verification**

**Validation:** answers “are we building the right system?”

**Verification:** answers “are we building the system right?”

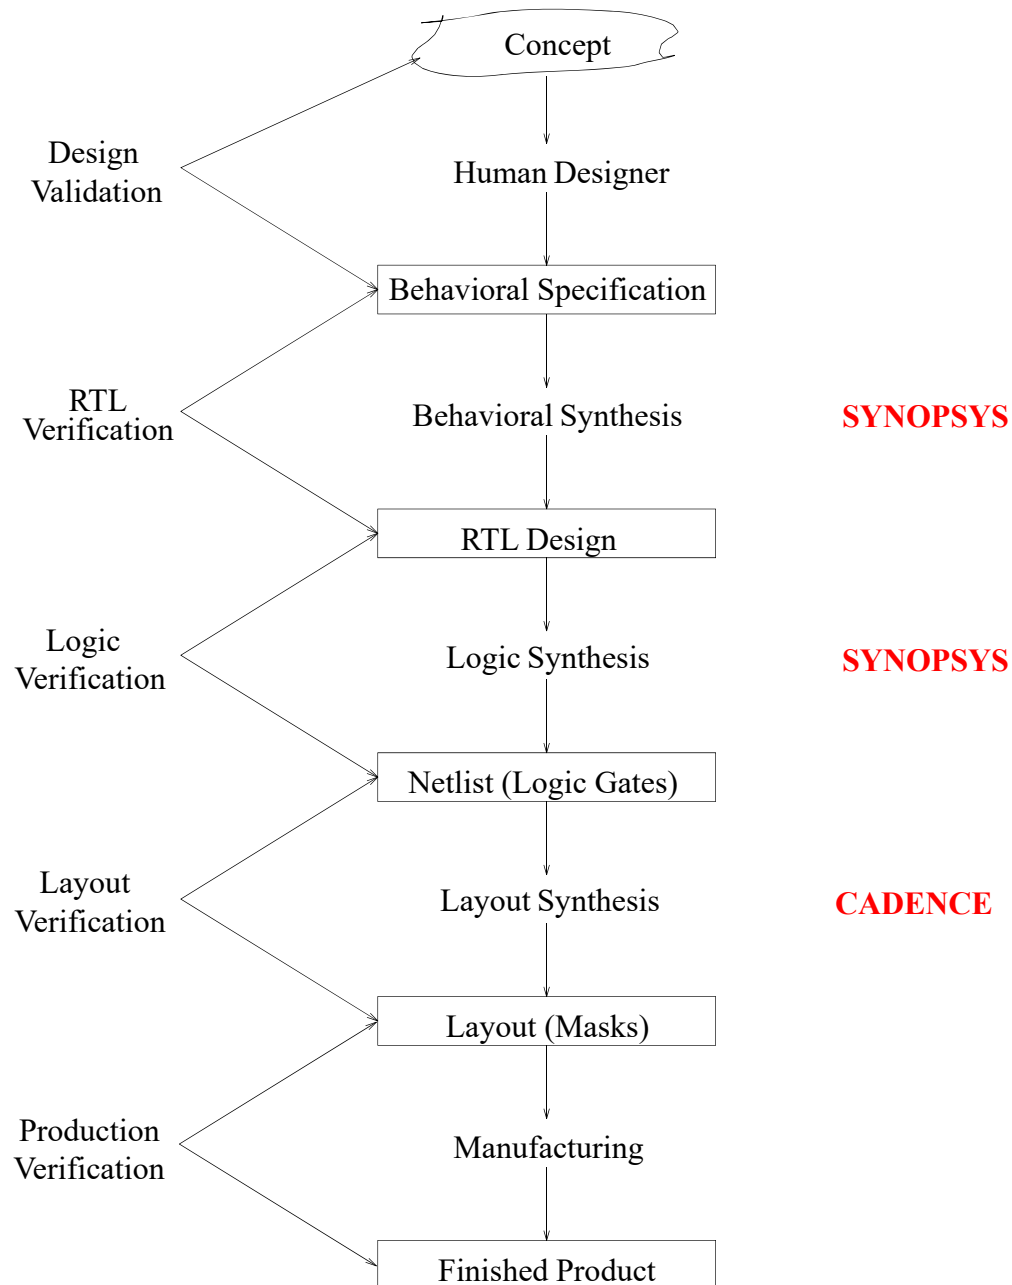

**Formal Validation:** Can we use logic to help ensuring that the specification is complete, consistent, and accurately captures the customer’s requirements

**Formal Verification:** Can we use logic to help ensuring that the system built faithfully implements its specification

Formal methods are used today in many **applications** including:

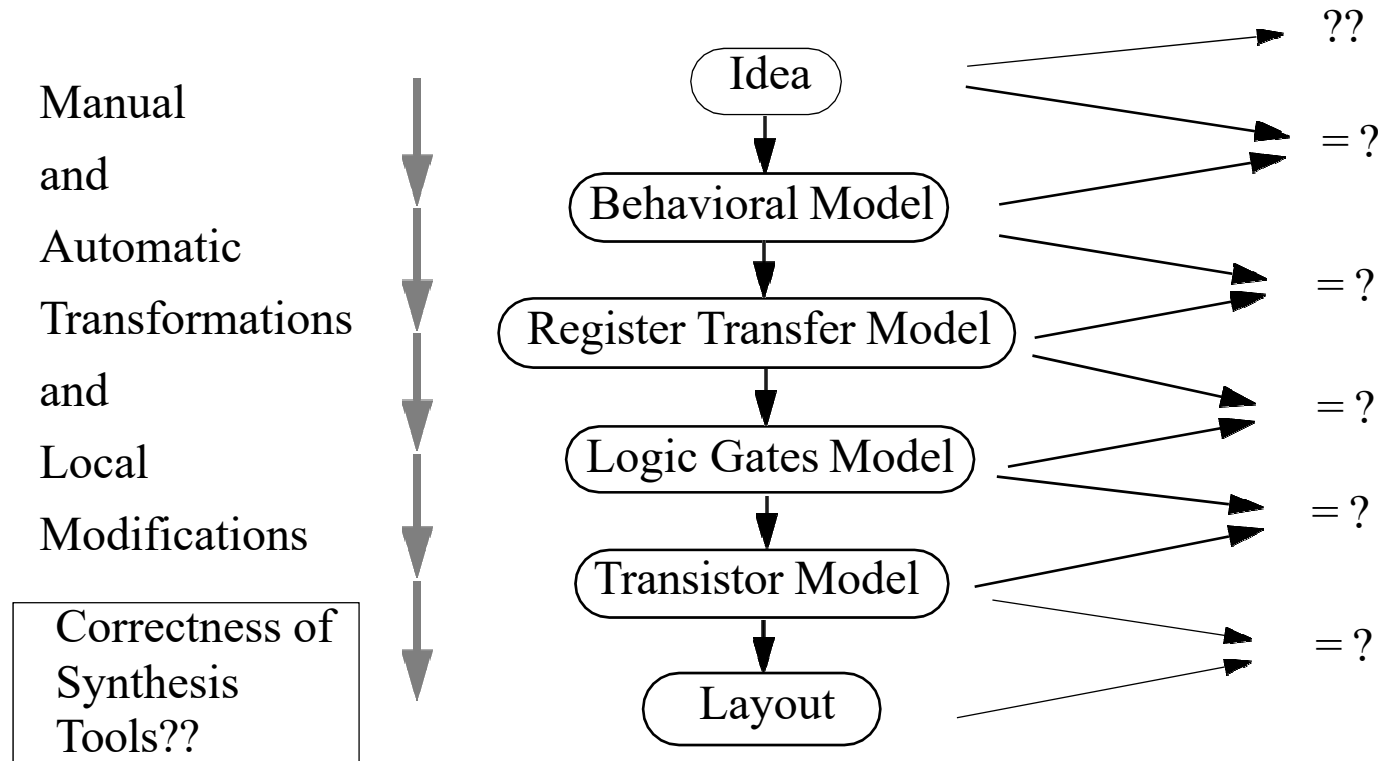

- Microprocessor Design
- Cache Coherency Protocols
- Telecommunications Protocols
- Rail and Track Signaling
- Security Protocols
- Automotive Companies

# VLSI Design Flow

# System Design and Verification

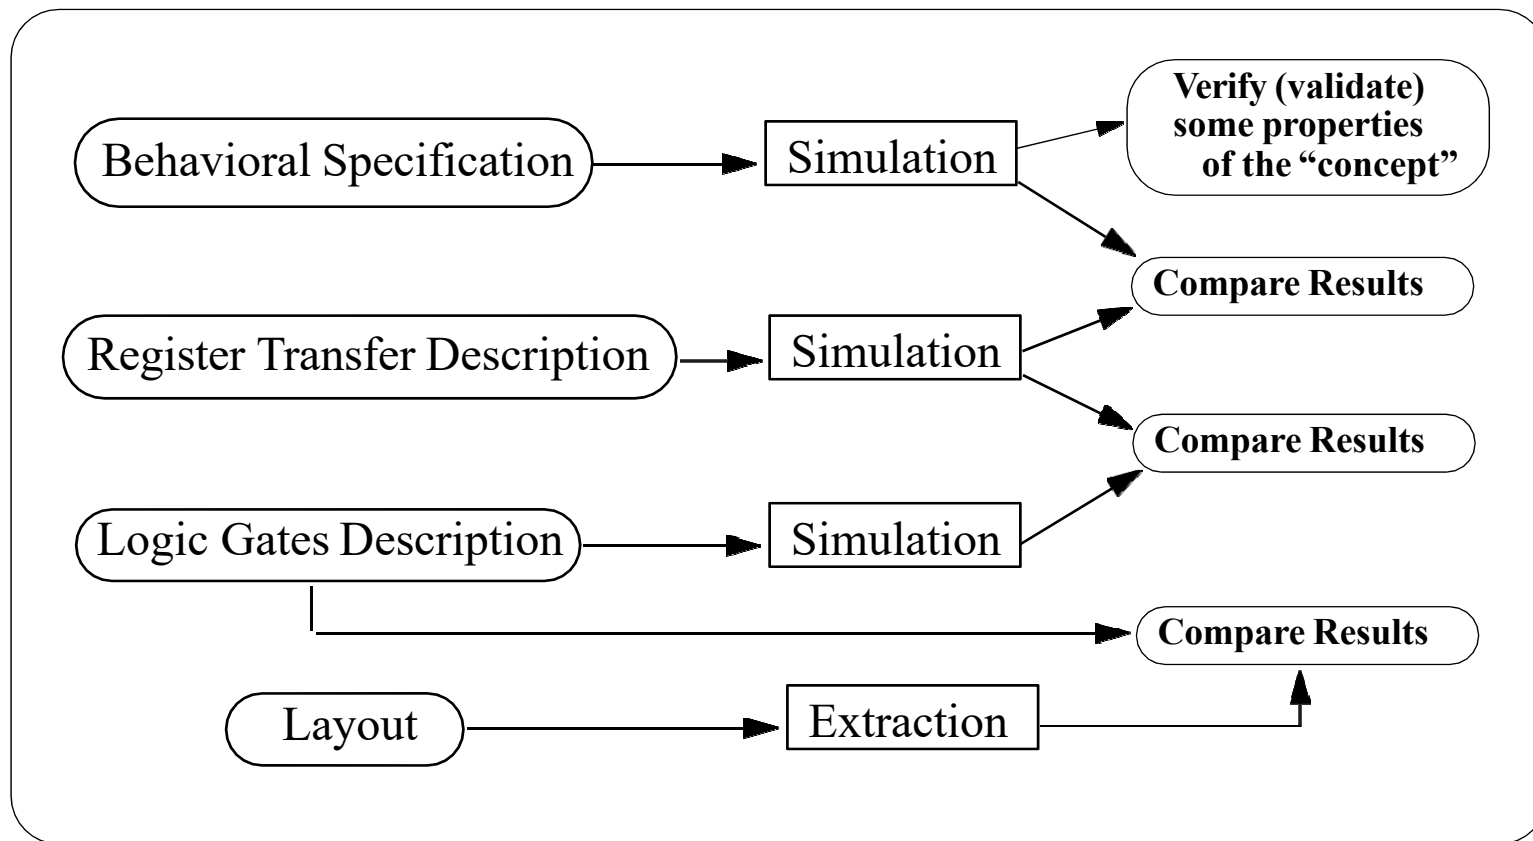

- Typical levels of abstraction in design:

- Behavioral synthesis: behavioral description into RTL description
- RTL synthesis: RTL description into logic description
- Logic synthesis: logic description into netlist of primitive gates for a target technology
- Layout synthesis: gate netlist to mask geometry

# Validation & Verification by Simulation

- *Traditionally* used to check for correct operation of systems
- Use of *test benches* (set of input vectors, expected outputs, environment constraints, etc.).

# Verification by Simulation (cont'd)

The “standard” verification technique is testing (simulation), but

*Program testing can be a very effective way to show the presence of bugs, but it is hopelessly inadequate for showing their absence.*

Edsger W. Dijkstra

**Bottom line:** Not feasible to simulate all input sequences to *completely* verify a design.

**Example 1:** Suppose you want to test a 64-bit floating-point division routine. There are  $2^{128}$  combinations. At 1 test/ $\mu$ s, it will take  $10^{25}$  years

**Example 2:** How long does it take to exhaustively simulate a 256 bit RAM?

$2^{256} = 10^{80}$  combinations of initial states and inputs

Assume

- Use all the matter in our galaxy ( $10^{17}$ kg) to build computers
- Each computer is of the size of single electron ( $10^{-30}$  kg)
- Each computer simulates  $10^{12}$  per second

$\Rightarrow 10^{10}$  years will reach **0.05%** of test cases!

# Verification by Simulation (cont'd)

## General Problems

- Generation of input sequences
  - Exercise a small fraction of system operations
  - Patterns developed manually
  - Weighted Random sequences to test certain functionality
- Generation of expected outputs
- Long simulation runs, effective input sequences hard to generate
  - Design coverage? Corner cases?
- Input patterns biased towards anticipated sources of errors
  - Errors often occur where not anticipated
  - Bugs typically introduced at locations to which designers did not pay attention
- Result comparison often incomplete: difficult to compare results from different models and simulators
- Systems growing larger: Number of possible states grows exponentially with increased number of possible event combinations
- Design teams growing larger: More sources of misunderstandings and inconsistencies

# Automated Synthesis: an Alternative to Simulation?

- An alternative to post-design verification is the use of *automated* synthesis techniques—*correct-by-construction*
- Logic synthesis techniques successful in automating low-level (gate-level) logic design
- Progress needed to automate the design process at *higher levels*.
- Until synthesis technology matures high-level design done manually
  - Requires post-design verification.
- Top-level specification/design must always be checked against properties of the “idea”
  - No golden reference at that level

# Formal Verification: Another Alternative to Simulation!

Formal Verification is the process of constructing a proof that a target system will behave in accordance with its specification.

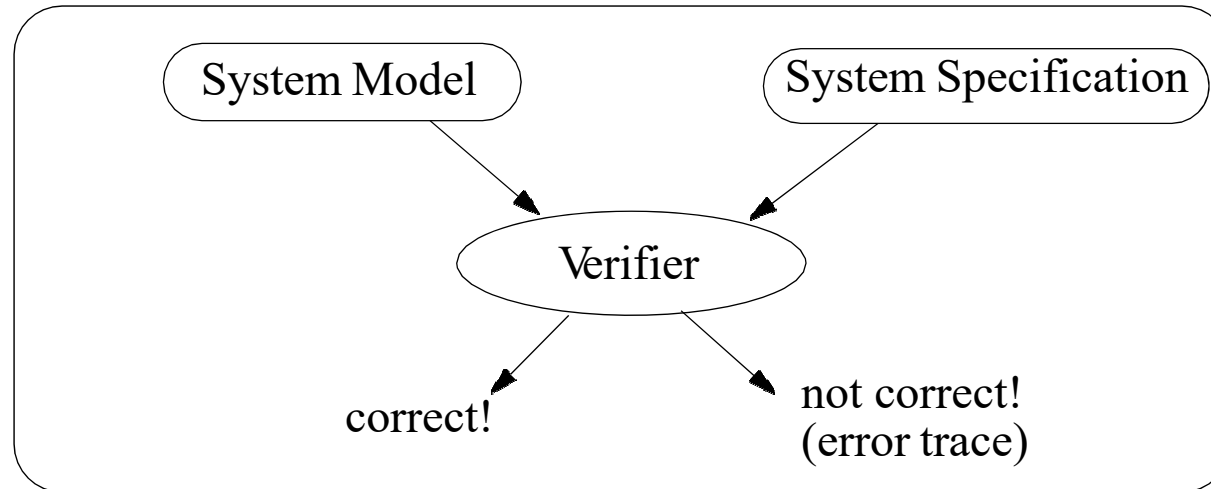

- Use of *mathematical reasoning* to prove that an implementation satisfies a specification
- Like a mathematical proof: correctness of a formally verified hardware design holds *regardless of input values*.
- Consideration of *all cases is implicit* in formal verification.
- Must establish:
  - A formal *specification* (properties or high-level behavior).
  - A formal description of the *implementation* (design at higher level of abstraction — *model* (observationally) equivalent to implementation or implied by implementation).

**[IEEE Spectrum, January 1996]**

“As designs grow ever more complex, formal verifiers have left the research lab for the production arena.”

“Formal methods have already proven themselves, and have a bright future in electronic design automation.”

# Formal Verification

- Complete with respect to a given property (!)
- Correctness guaranteed mathematically, regardless the input values
- No need to generate expected output sequences
- Can generate an error trace if a property fails: better understand, confirm by simulation
- Formal verification useful to detect and locate errors in designs
- Consideration of *all cases is implicit* in formal verification

# Simulation vs. Formal Verification

**Example:**  $(x+1)^2 = x^2 + 2x + 1$

**Simulation Values:**

$x$	$(x+1)^2$	$x^2 + 2x + 1$
0	1	1
1	4	4
2	9	9
3	16	16
9	100	100
67	4624	4624
...	...	...

# Simulation vs. Formal Verification (cont'd)

## Formal Proof

1.	$(x + 1)^2 = x^2 + 2x + 1$	definition of square
2.	$(x + 1)(x + 1) = (x + 1)x + (x + 1)1$	distributivity
3.	$(x + 1)^2 = (x + 1)x + (x + 1)1$	substitution of 2. in 1.
4.	$(x + 1)1 = x + 1$	neutral element 1
5.	$(x + 1)x = xx + 1x$	distributivity
6.	$(x + 1)^2 = xx + 1x + x + 1$	substitution of 4. and 5. in 3.
7.	$1x = x$	neutral element 1
8.	$(x + 1)^2 = xx + x + x + 1$	substitution of 7. in 6.
9.	$xx = x^2$	definition of square
10.	$x + x = 2x$	definition of 2x
11.	$(x + 1)^2 = x^2 + 2x + 1$	<b>substitution of 9. and 10. in 8.</b>

# Simulation vs. Formal Verification

- Simulation: *complete* (real) **model**, *partial verification*  
Verification: *partial* (abstract) **model**, *complete verification*
- Simulation still needed to tune specifications; for large complete designs
- Verification can generate counter-examples (error traces); possibly false negatives!
- Techniques are complementary — formal verification gives additional confidence, *e.g.*,
  1. Apply formal verification of abstract model
  2. Obtain error trace if bug found (may be false negative!)
  3. Simulate error trace on the real model
- Common difficulty in all verification methods:
  - lack of “golden” reference
  - what properties to verify .....

**[IEEE Spectrum, January 1996]**

*“Simulation and formal verification have to play together.”*

# Hierarchical Verification

- **Specification (Spec):**
  - Properties*: enumeration of assumptions and requirements,
  - Functions*: desired behavior or design descriptions,
  - State machines*: desired behavior or design descriptions,
  - Timing requirements*, etc.
- **Implementation (Imp)** refers to the design to be verified.
  - Corresponds to a description at any level of abstraction, not just the final physical level.
  - Can serve as a specification for the next lower level.

# Formal Specification

- A *specification* is a description of a system and its desired properties
- Useful as a communication device:
  - between customer and designer,
  - between designer and implementor, and
  - between implementors and tester
- Companion document to the system's source code, but at a higher level of abstraction
- Properties relate to **function**, interfaces, timing, performance, power, layout, etc.
- *Formal specification*:
  - Use of formal methods (a **language** with mathematically-defined **syntax** and **semantics**) to describe the intended behavior of the system:
  - The language of logic provides an unambiguous method of recording the specification
  - We can reason about a formal specification to check that the system specified will possess other desired properties
- The process of writing a formal specification helps uncover ambiguity and incompleteness
- Formal specifications most successful for functional behavior, also interface & timing
- Trend to integrate different specification languages, each for a different aspect (e.g. VERA, SystemC, VHDL+)

# Formal Specification (cont'd)

## Specification Validation

- Whether the specification means what it is intended to mean
- Whether it expresses the required properties
- Whether it completely characterizes correct operation, etc.

(Validation methods: simulation or formal techniques)

## Formalisms for representing specifications:

- Logic: propositional, first-order predicate, higher-order, modal (temporal), etc.
- Automata/language theory: finite state, omega automata, etc.

## Types of properties:

- Functional correctness properties;
- Safety (invariant) and Liveness properties

E.g.: in a mutual exclusion system with two processes A and B

*Safety property* (**nothing bad will ever happen**): e.g. simultaneous access will never be granted to both A and B. If false, can be detected by finite sequences

*Liveness property* (**something good will eventually happen**): e.g. if A wants to enter its critical section, it will eventually do so. Can only be proved false by infinite sequences (any finite sequence can be extended to satisfy the eventuality condition)

# Limitations of Formal Verification

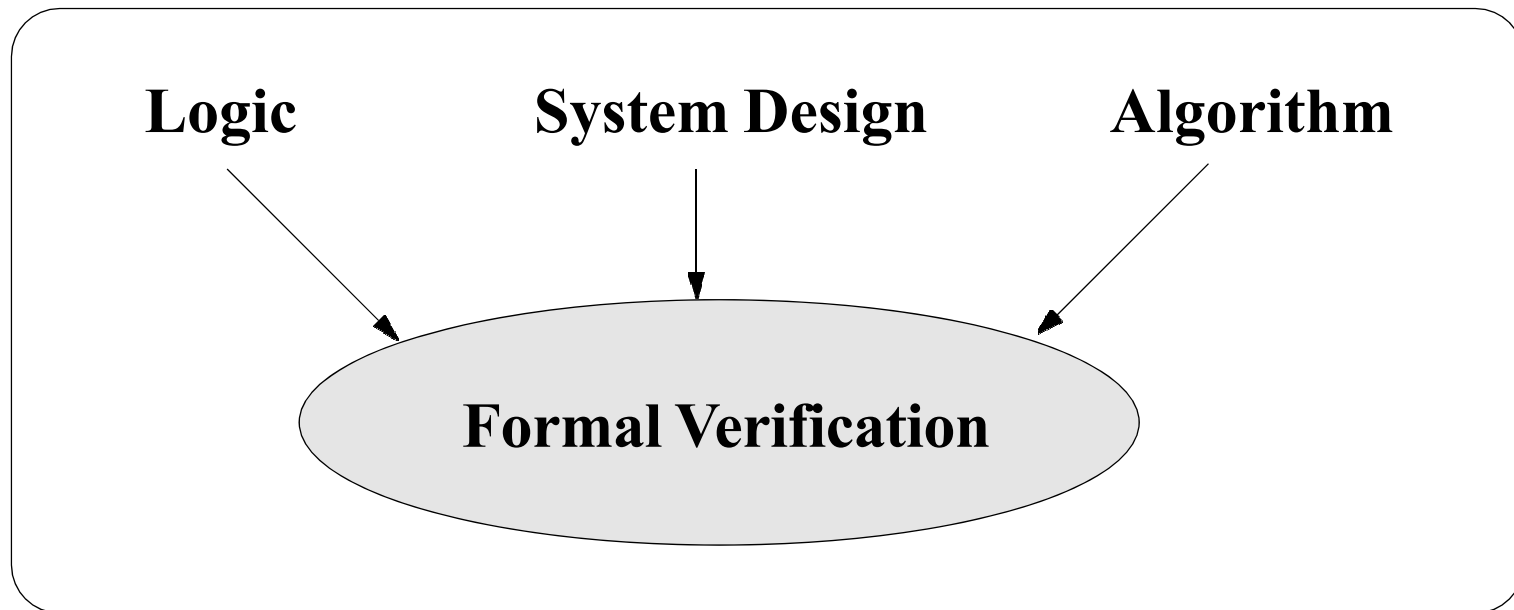

Just because we have proved something correct does not mean it will work!

There are gaps where formal verification connects with the real world.

- Does the **specification** actually captures the designer's intentions?
  - Specification must be simple and abstract
  - Example of a good specification for a half-adder:  $out = (in_1 + in_2) \bmod 2$
- Does the **implementation** in the real world behave like the model?
  - Can  $in_1$  drive three inputs
  - What happens if the wires are fabricated too close together?
  - Do we need to model quantum effects on the silicon surface?

# Formal Verification — an Interdisciplinary Activity

- Formal methods cut across almost all areas in Computer Science and Engineering
- Foundation in mathematics
- Formal verification requires
  - A formal language for describing both specifications and implementations
  - A deductive calculus for providing propositions in this language

# State of the Art

- In the 1960-70's, high expectations for “software verification”, but hopes gradually fizzled out by the late 1970's
- Theorem proving approaches have “cultural roots” in software verification in 1970's (Hoare, Owicki, Gries)
- The use of formal methods did not seem practical
  - notations too obscure
  - techniques did not scale with problem size
  - tool support inadequate or too hard to use
  - Only a few non-trivial case studies available
  - Few people had the necessary training
- Why formal methods might work well for “hardware verification”?
  - Hardware is often regular and hierarchical
  - Re-use of design is common practice
  - Hardware specification is more common, e.g., VHDL models
  - Primitives are simpler, e.g., behavior of an NAND-Gate easier to describe than the semantics of a while-loop
  - Cost of design error can mean a 6 months delay and a costly set of lithography masks

# State of the Art (cont'd)

- Recently more promising picture
  - Software specification: industry trying out notations like SDL or Z to document system's properties
  - Protocol verification successful
  - Hardware verification: industry adopting model checking and some theorem proving to complement simulation
  - Industrial case studies increasing confidence in using formal methods
  - Verification groups: *IBM, Intel, Motorola, Apple, Google, Fujitsu, Cadence, Siemens, Synopsys, .....*
  - Commercial tools from: *Cadence, Synopsys, IBM, .....*
- In this course, we focus on formal verification methods of digital hardware
- ... but model checking is making inroads into software verification of real-time reactive systems and protocols

# Formal Logic

## What Does “Formal” mean?

- Webster’s dictionary gives the following as one of the definitions of “*formal*”:  
“related to, concerned with, or constituting the outward **form** of something as distinguished from its **content**”
- A method is **formal** if its rules for manipulation are based on form (*syntax*) and not on content (*semantics*)
- Majority of existing formal techniques are based on some flavor of formal (symbolic) logic: Propositional logic, Predicate logic, other logics.

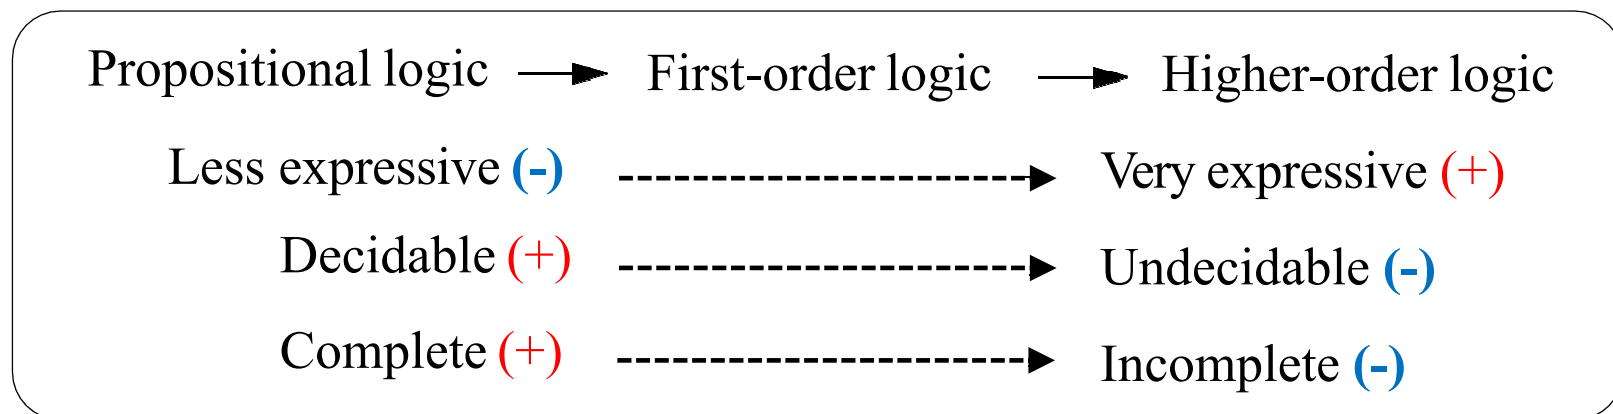

## Formal logic

- Every logic comprises a formal language for making statements about objects and reasoning about properties of these objects.
- Statements in a logic language are constructed according to a predefined set of formation rules (depending on the language) called *syntax rules*.
- A logic language can be used in different ways.

# Types of Logic

- Propositional logic: traditional *Boolean* algebra, variables  $\in \{0,1\}$
- First-order logic (Predicate logic): quantifies *for all* ( $\forall$ ) and *there exists* ( $\exists$ ) over variables
- Higher-order logic: adds reasoning about (quantifying over) sets and functions (predicates)
- Modal/temporal logics: reason about what *must* or *may* happen

- Propositional logic: decidable and complete
- First-order logic: decidable but not complete
- Higher-order logic: not decidable nor complete

# Formal Logic (cont'd)

## Proof Theory

- A formal logic system consists of:
  - a notation (syntax)
  - a set of axioms (facts)
  - a set of inference (deduction) rules
- A formal proof is a sequence of statements where every statement follows from a preceding one by a rule of inference
- Purely syntactic (mechanical) activity; not concerned with the meaning of statements, but with the arrangement of these statements, and whether proofs can be constructed

## Model Theory

- The second use of a logic language is for expressing statements that receive a meaning when given an interpretation
- The language of logic is used here to formalize properties of structures, to determine when a statement is true on a structure
- This use of a logic language is called *model theory*
- Forces a *precise* and *rigorous* definition of the concept of *truth* on a structure

# Formal Logic (cont'd)

## Logic = Syntax + Semantics

- Syntax and semantics of logic are not independent
- A logic language has a syntax, and the meaning of statements by an interpretation on a structure
- The interaction between model theory and proof theory *makes logic an interesting and effective tool*

## Proof System

- Given a logic (syntax and semantics), there can be one or more proof systems, e.g. HOL and PVS are two proof systems based on higher-order logic.

## Issues of proof systems

- **Consistency (Soundness)**: all provable formulas (*theorems*) are logically (*semantically*) true
  - **Completeness**: all valid formulas (*semantically true*) are provable (*theorems*)
  - **Decidability**: there is an algorithm for deciding the (*semantical*) truth of any formula (*theorems*)
- ⇒ A proof system is acceptable only if it is consistent (may not be complete nor decidable)

# Formal Logic (cont'd)

## Application of logic to verification

- *Specification* represented as a *formula*
- *Implementation* represented as a *formula* or as a *semantic model*
- **Formula  $\vdash$  Formula:**  
Verification as theorem proving, i.e., relationship (implication or equivalence) between the specification and the implementation is a theorem to be proven.
- **Model  $\models$  Formula:**  
Both theorem proving and model checking can be used  
*Model checking* deals with the semantic relationship: shows that the implementation is a model for the specification formula (property).

## Relation between Spec and Imp:

- $\text{Imp} \equiv \text{Spec}$ : the implementation is *equivalent* to the specification
- $\text{Imp} \rightarrow \text{Spec}$ : the implementation *logically implies* the specification
- $\text{Imp} \models \text{Spec}$ : the implementation is a *semantic model* in which the specification is true

# Formal Verification Methods

Formal verification methods can be categorized in following main groups:

## *Interactive (deductive) Methods:*

- **Theorem Proving**: relationship between a specification and an implementation is a theorem in a logic, to be proven within the context of a proof calculus

## *Automated Methods:*

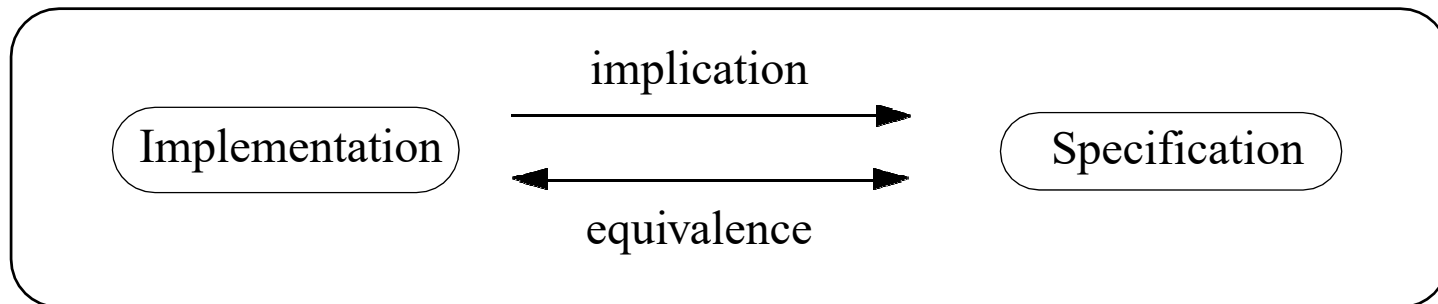

- **Combinational Equivalence Checking**: proof of structural equivalence of logic designs
- **Sequential Equivalence Checking**: proof of behavioral equivalence of FSMs
- **Model Checking**: proof of (temporal) logic property (safety & liveness) against a semantic model of the design
- **Invariant Checking** (safety property)
- **Language Containment** (model checking of w-automata)

# Issues in Verification methods

- **Soundness:** every statement that is provable is actually true.
- **Completeness:** every statement that is actually true is provable.
- **Automation:** proof generation process automatic, semi-automatic or user driven
- Can it handle:
  - Compositional proofs:* constructed syntactically from proofs of component parts
  - Hierarchical proofs:* for system organized hierarchically at various levels of abstraction
  - Inductive proofs:* reason inductively about parameterized descriptions

# Theorem Proving

Prove that an implementation satisfies a specification by mathematical reasoning.

Implementation and specification expressed as *formulas* in a *formal logic*.

Relationship (logical equivalence/logical implication) described as *a theorem* to be proven.

## **A proof system:**

A set of axioms and inference rules (simplification, rewriting, induction, etc.)

# Theorem Proving (cont'd)

## Some known theorem proving systems:

Boyer-Moore/ACL2 (first-order logic)

HOL (higher-order logic)

PVS (higher-order logic)

Lambda (higher-order logic)

## Advantages:

- High abstraction and powerful logic expressiveness
- Unrestricted applications
- Useful for verifying parameterized datapath-dominated circuits

## Limitations:

- Interactive (under user guidance)
- Requires expertise for efficient use
- Automated for narrow classes of designs

# FSM-based Methods

## Finite State Machines (FSM)

- Well-developed theory for analyzing FSMs (e.g., reachable states, equivalence)
- An FSM  $(I, O, S, \delta, \lambda, S_0)$ 
  - I : input alphabet,
  - O: output alphabet,
  - S: set of states,
  - $\delta$ : next-state relation,  $\delta \subseteq S \times I \times S$ ,
  - $\lambda$ : output relation,  $\lambda \subseteq S \times I \times O$  (Mealy),  $\lambda \subseteq S \times O$  (Moore)
  - $S_0$ : set of initial states.
- Deterministic machines:  $\delta: S \times I \rightarrow S$  and  $\lambda: S \times I \rightarrow O$  are functions,  $S_0 = \{s_0\}$ .

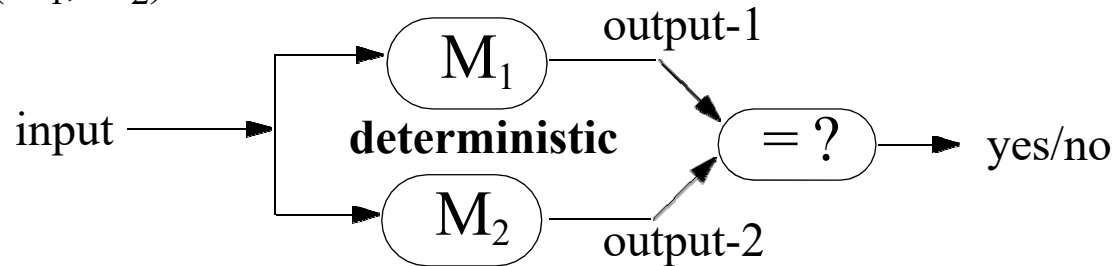

## FSM Equivalence Verification

- Basic method:
  - If same state variables — *Combinational Equivalence* of  $\delta$  and  $\lambda$
  - If state space different - *State Enumeration by Reachability Analysis*  
Two FSMs are equivalent if they produce the same output for every possible input sequence — *Sequential Equivalence Checking*

# Equivalence Checking

## Equivalence by reachability analysis of the Product Machine

Product Machine  $M = (M_1, M_2)$

### Reachability Analysis:

Start from initial state

**repeat**

Apply transition relation to determine next state

In each reached state, check equivalence of corresponding outputs of  $M_1, M_2$

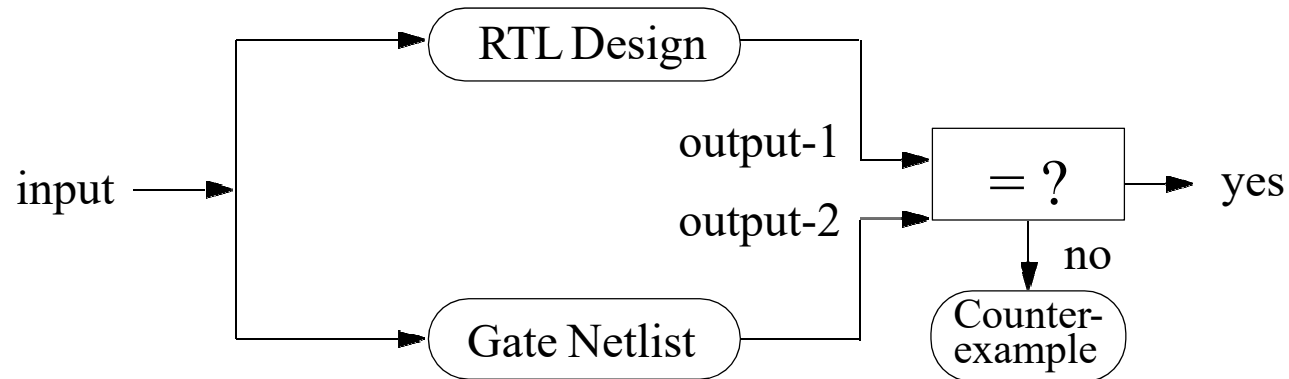

**until** all reachable states visited

- Involves building a *state transition graph* (*Finite Kripke structure*)
- Problem: “State explosion” - e.g., 32-bit → register  $2^{32}$  states
- Partial solution: Implicit State Enumeration with
  - Reduced Ordered Binary Decision Diagrams (ROBDD)

Represent transition/output relations and sets of states symbolically using ROBDD

# Equivalence Checking (cont'd)

## Application example:

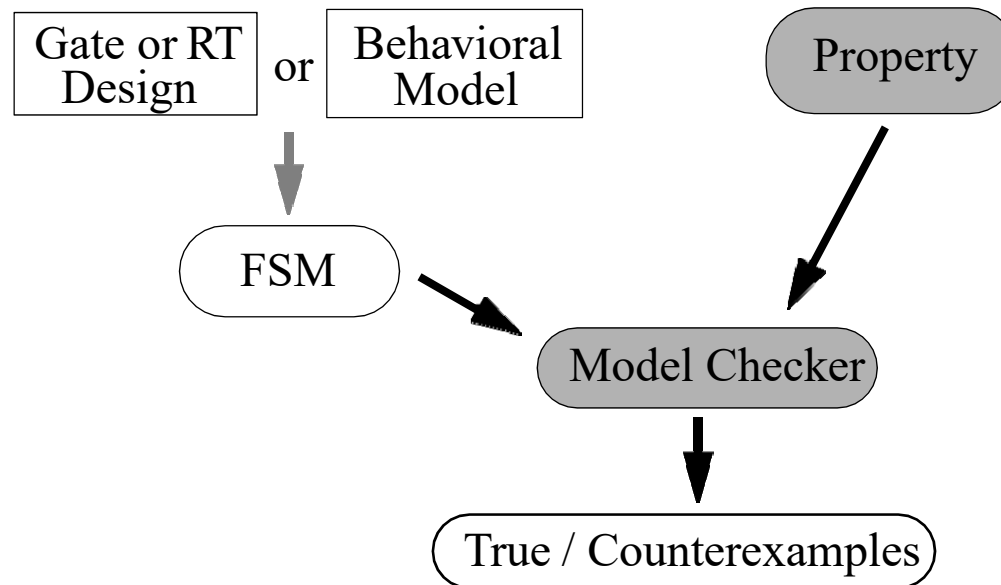

## Combinational equivalence:

- possible if one-to-one state mapping do exist
- relatively straightforward (equivalence of sets of functions (BDDs))
- tools already part of verification flow

## Sequential equivalence:

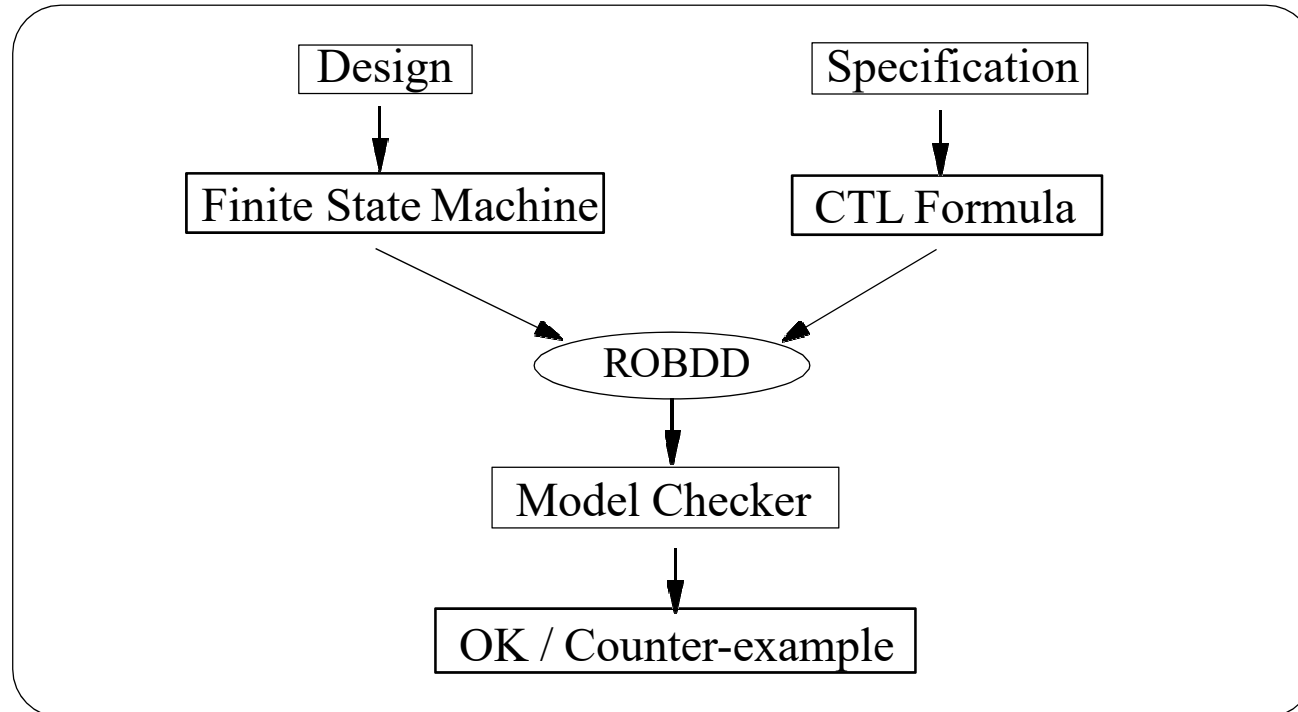

- no state mapping required (building of product machine)
- hard to handle large circuits (also must consider all initial states)
- no tools for industrial use

# Model Checking

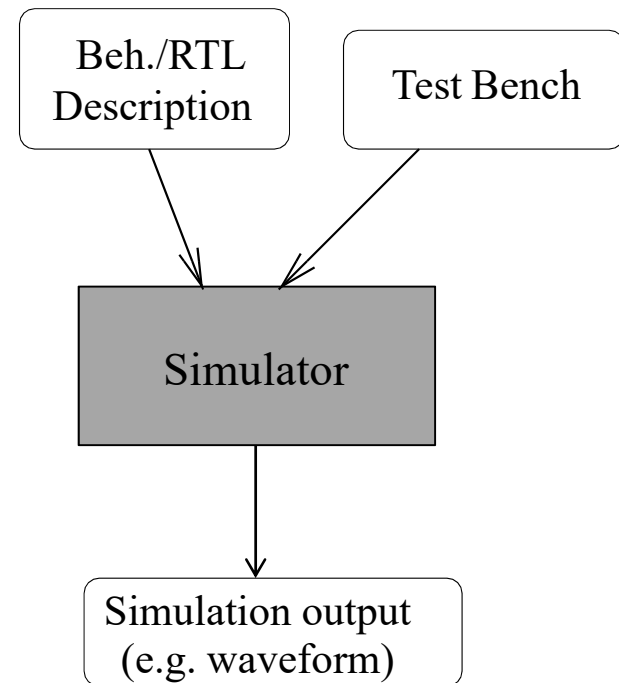

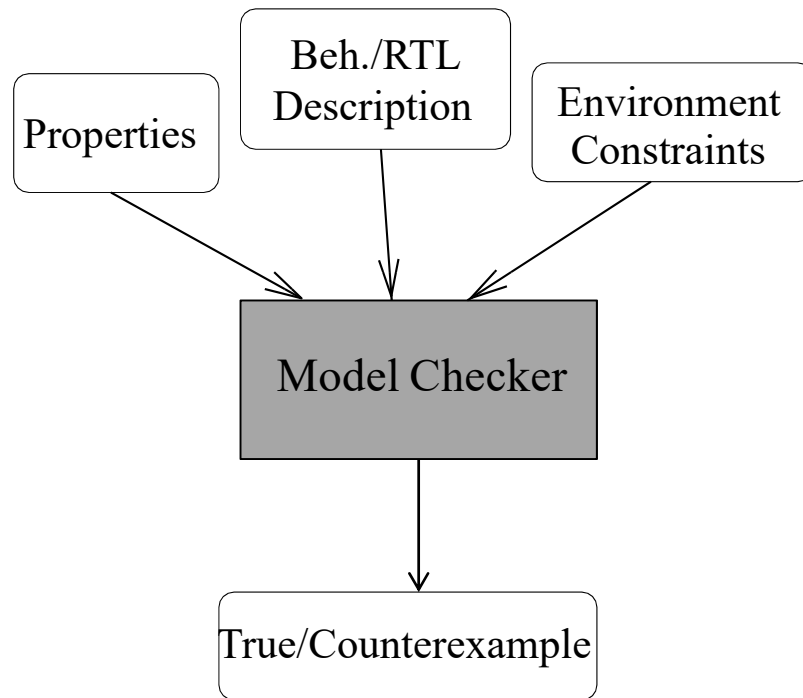

- Property described by temporal logic formula.
- System modeled by Labeled Transition Graph (LTG, LTS, *Finite Kripke structure*).
- *Exhaustive* search through the state space of the system (*Reachability Analysis*) to determine if the property holds (provides counterexamples for identifying design errors).
- Problem: “State explosion”
- Partial Solution: Symbolic Model Checking  
Represent transition/output relations and sets of states symbolically using ROBDD

# Symbolic Model Checking

- Problem: again “State explosion” (max ~ 400 Boolean variables), low abstraction level.

# Model Checking vs. Simulation

# Theorem Proving vs. Model Checking

**Theorem Proving:** useful for architectural design and verification

Process: Implementation description: Formal logic

Specification description: Formal logic

Correctness:  $\vdash Imp \Rightarrow Spec$  (implication) or  $\vdash Imp \Leftrightarrow Spec$  (equivalence)

- High abstraction level possible, expressive notation, powerful logic and reasoning
- Interactive and deep understanding of design and higher-order logic required
- Need to develop rules (lemmas) and tactics for class of designs
- Need a refinement method to synthesizable VHDL / Verilog

**Model Checking:** at RT-level (or below) with at most ~400 Boolean state variables

- Process: Implementation description: Model as FSM

Specification description: Properties in temporal logic

Correctness:  $Impl \models Spec$  (property holds in the FSMmodel)

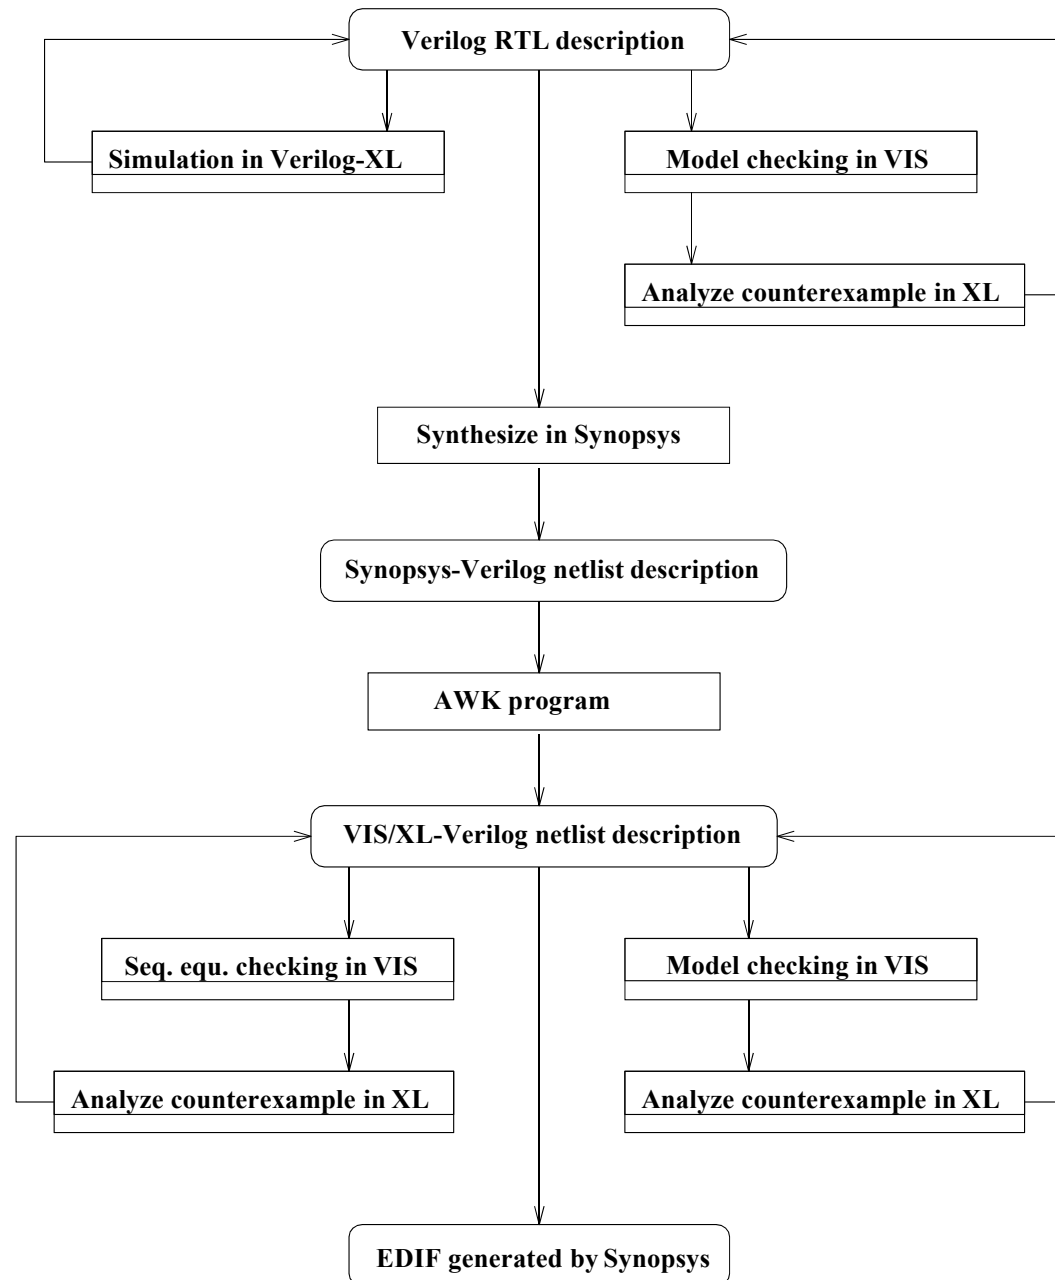

- Easy to learn and apply (completely automatic), properties must be carefully prepared
- Integrated with design process, refinement from skeletal model
- State space explosion problem (not scalable to large circuits)
- Increase confidence, better verification coverage
