

# Handbook on the Physics and Chemistry of Rare Earths, volume 27

Elsevier, 1999

Edited by: Karl A. Gschneidner, Jr. and LeRoy Eyring  
ISBN: 978-0-444-50342-8

## PREFACE

Karl A. GSCHNEIDNER, Jr., and LeRoy EYRING

---

*These elements perplex us in our rearches [sic], baffle us in our speculations, and haunt us in our very dreams. They stretch like an unknown sea before us – mocking, mystifying, and murmuring strange revelations and possibilities.*

Sir William Crookes (February 16, 1887)

---

This volume of the *Handbook* is the last volume to be published with a 19xx imprint and contains three chapters which deal with rare earth alloys and intermetallic compounds.

Chapter 173 is by P.S. Salamakha, O.L. Sologub and O.I. Bodak and deals with ternary rare-earth–germanium alloys – their phase diagrams and the crystal structures of the intermediate phases. The largest number of intermetallic phases are found in the Group-VIII metals, i.e. iron, cobalt and nickel and their congeners ruthenium, rhodium and palladium. Although there is a paucity of data for the congeners in the third row of transition metals, the little information available indicates that osmium, iridium and platinum will also form as many intermetallic compounds. Of the group-VIII metals the first member of each row (iron, ruthenium and osmium) forms only about half (10) the number of compounds as the other two members, cobalt and nickel and their congeners.

Another interesting observation is that the ternary alloy systems of the rare earths and germanium with the s and p elements have hardly been investigated. And of those that have been studied, only a few intermediate phases have been observed in the ternary systems. The chapter ends with a discussion of the general trends and unusual features observed in the various sets of ternary phase diagrams.

In a companion chapter (174) P.S. Salamakha describes in detail the various structure types that have been adopted by the rare-earth–germanium ternary intermetallic compounds. The correlations, crystal chemistry and interrelationships of the 135 structure types are discussed. Two distinct behaviors are found depending on the nature of the outer bonding electrons: the p elements behave differently from the s and d elements, which behave similarly. When the third component is a p element the compounds maintain the same R to Ge ratio as found in the binary  $R_xGe_y$  phases, e.g.  $RGe_2$  and  $R_3Ge_5$ , where R is a rare earth metal. As one might expect many of the compounds have variable composition at a constant R content. For the s and d metals the compounds tend to fall on lines

connecting the three elements with binary phases of simple compositions, such as the R–MGe, M–RGe<sub>2</sub>, Ge–RM lines, where M is an element other than R or Ge. The line connecting the RM<sub>2</sub>–RGe<sub>2</sub> binary phases also has several phases lying on it, including RMGe. The equiatomic composition RMGe has 20 known structure types.

Quaternary compounds and superstructures are also reviewed by Salamakha.

The last chapter (175) deals with scandium alloys and intermetallic compounds – binary, ternary and higher order systems. In their review B.Ya. Kotur and E. Gratz summarize the various phase diagrams of scandium systems and present the crystal structure properties of the various intermediate phases. The general trends observed in the phase relationships and crystal chemistry of these materials are discussed, and may be useful in finding new scandium phases. In the last section of their chapter Kotur and Gratz present physical property data on scandium intermetallic phases. The results are divided into three groups – compounds which have (1) a magnetic ground state, (2) a superconducting ground state and (3) those with neither a magnetic or a superconducting ground state.

## CONTENTS

Preface v

Contents vii

Contents of Volumes 1–26 ix

173. P.S. Salamakha, O.L. Sologub and O.I. Bodak  
*Ternary rare-earth–germanium systems* 1

174. Petro S. Salamakha  
*Crystal structures and crystal chemistry of ternary rare-earth germanides* 225

175. Bogdan Ya. Kotur and Ernst Gratz  
*Scandium alloy systems and intermetallics* 339

*Author index* 535

*Subject index* 553

## CONTENTS OF VOLUMES 1–26

### VOLUME 1: Metals

1978, 1st repr. 1982, 2nd repr. 1991; ISBN 0-444-85020-1

1. Z.B. Goldschmidt, *Atomic properties (free atom)* 1
2. B.J. Beaudry and K.A. Gschneidner Jr, *Preparation and basic properties of the rare earth metals* 173
3. S.H. Liu, *Electronic structure of rare earth metals* 233
4. D.C. Koskenmaki and K.A. Gschneidner Jr, *Cerium* 337
5. L.J. Sundström, *Low temperature heat capacity of the rare earth metals* 379
6. K.A. McEwen, *Magnetic and transport properties of the rare earths* 411
7. S.K. Sinha, *Magnetic structures and inelastic neutron scattering: metals, alloys and compounds* 489
8. T.E. Scott, *Elastic and mechanical properties* 591
9. A. Jayaraman, *High pressure studies: metals, alloys and compounds* 707
10. C. Probst and J. Wittig, *Superconductivity: metals, alloys and compounds* 749
11. M.B. Maple, L.E. DeLong and B.C. Sales, *Kondo effect: alloys and compounds* 797
12. M.P. Dariel, *Diffusion in rare earth metals* 847
- Subject index 877

### VOLUME 2: Alloys and intermetallics

1979, 1st repr. 1982, 2nd repr. 1991; ISBN 0-444-85021-X

13. A. Iandelli and A. Palenzona, *Crystal chemistry of intermetallic compounds* 1
14. H.R. Kirchmayr and C.A. Poldy, *Magnetic properties of intermetallic compounds of rare earth metals* 55
15. A.E. Clark, *Magnetostrictive RFe<sub>2</sub> intermetallic compounds* 231
16. J.J. Rhyne, *Amorphous magnetic rare earth alloys* 259
17. P. Fulde, *Crystal fields* 295
18. R.G. Barnes, *NMR, EPR and Mössbauer effect: metals, alloys and compounds* 387
19. P. Wachter, *Europium chalcogenides: EuO, EuS, EuSe and EuTe* 507
20. A. Jayaraman, *Valence changes in compounds* 575
- Subject index 613

### VOLUME 3: Non-metallic compounds – I

1979, 1st repr. 1984; ISBN 0-444-85215-8

21. L.A. Haskin and T.P. Paster, *Geochemistry and mineralogy of the rare earths* 1
22. J.E. Powell, *Separation chemistry* 81
23. C.K. Jørgensen, *Theoretical chemistry of rare earths* 111
24. W.T. Carnall, *The absorption and fluorescence spectra of rare earth ions in solution* 171
25. L.C. Thompson, *Complexes* 209
26. G.G. Libowitz and A.J. Maeland, *Hydrides* 299
27. L. Eyring, *The binary rare earth oxides* 337
28. D.J.M. Bevan and E. Summerville, *Mixed rare earth oxides* 401
29. C.P. Khattak and F.F.Y. Wang, *Perovskites and garnets* 525
30. L.H. Brixner, J.R. Barkley and W. Jeitschko, *Rare earth molybdates (VI)* 609
- Subject index 655

**VOLUME 4: Non-metallic compounds – II**

1979, 1st repr. 1984; ISBN 0-444-85216-6

31. J. Flahaut, *Sulfides, selenides and tellurides* 1
32. J.M. Haschke, *Halides* 89
33. F. Hulliger, *Rare earth pnictides* 153
34. G. Blasse, *Chemistry and physics of R-activated phosphors* 237
35. M.J. Weber, *Rare earth lasers* 275
36. F.K. Fong, *Nonradiative processes of rare-earth ions in crystals* 317
- 37A. J.W. O'Laughlin, *Chemical spectrophotometric and polarographic methods* 341

## Symbols and abbreviations

$a, b, c$	Unit cell dimensions (in nm)	$X_R$	Electronegativity of the R component
at.%	Composition in atomic percent	$\alpha, \beta, \gamma$	unit cell angles (in degrees)
h	Hours	~	Precedes the composition formula of a compound to indicate that the composition is given approximately
M	s-, p-, d-, f-element		
O	Orthorhombic structure		
R, R'	Rare-earth metal, Y, Sc, and the lanthanides		
$r_R$	Atomic radius of the R component		
T	Tetragonal structure		
$x$	indicates variable component contents, when it is used as index in compound compositional formula. The expression $N-x$ (where $N$ is a number) means $N$ minus $x$ , with the $x$ value given in the text		

---

## 1. Introduction

The aim of this chapter is to systematize the current knowledge concerning phase diagrams and crystal structures of ternary metal germanides with the R elements (R  $\equiv$  Sc, Y, and the lanthanides). The isothermal sections for the ternary R–s, p, d, f element–Ge systems have been extensively studied in recent years by the researchers at the Inorganic Chemistry Department at Lviv University. The crystal structure of ternary compounds has been investigated by various groups of authors. The present status of information on phase diagrams and formation of rare-earth metal germanides is summarized in tables 1, 2 and 3.

This review consists of six sections. Sections 2–5 review the literature published on the systems, i.e., isothermal sections and crystallographic characteristics of ternary compounds, and outline the experimental methods that have been utilized. All lattice parameter values in this chapter are reported in nm units. The literature was searched back to the year 1966.

The phase diagrams of R–M–Ge systems presented in the following sections are listed in the order of Mendeleevs Table, and divided into four major groups:

- R–s element–Ge systems. In this group, lithium-containing ternary systems are the most studied (see table 1).
- R–p element–Ge systems. As one can see from table 1, information on these systems is still scarce. Phase diagrams have been investigated for only a few ternary R–M–Ge combinations.
- R–d element–Ge systems. Phase diagrams have been established for a large number of possible combinations, and crystal structures have been determined for a majority of compounds observed (table 2).

Table 1  
Formation of ternary compounds and phase equilibria within ternary R-s,p element-Ge systems<sup>a</sup>

	Li	Na	K	Rb	Cs	Be	Mg	Ca	Sr	Ba	B	Al	Ga	In	Tl	C	Si	Sn	Pb	P	As	Sb	Bi
Sc	1											1											
Y	3										0 ■	3 ▲	5	1		1	2 ■

Tm	4 ■											2	8			1							
Yb	4 ▲						1					3		1									
Lu	4 ■											2				1							

<sup>a</sup> The number in a table cell corresponds to the number of ternary germanide compounds observed; a solid square indicates that a complete isothermal section has been established; a solid triangle indicates that a partial isothermal section has been established.

<sup>a</sup> The number in a table cell corresponds to the number of ternary germanide compounds observed; a solid square indicates that a complete isothermal section has been established.

(d) R–f element–Ge systems. Isothermal sections were constructed for a small number of ternary R–R'–Ge systems (table 3).

The general features and tendencies in the R–s, p, d, f element–Ge systems are discussed in sect. 6.

A detailed description of the structure types and crystal chemistry of ternary germanides will found in the next chapter (174) of this volume; the physical properties of ternary germanides are not included in the present review.

## 2. Rare-earth–s element–germanium systems

### 2.1. R–Li–Ge systems

#### 2.1.1. Sc–Li–Ge

The only piece of information available on the interaction of components in the Sc–Li–Ge system is due to the work of Grund (1985) who identified and characterized by X-ray powder diffraction the compound ScLiGe (MgAgAs type,  $a=0.6407$ ). Sample was obtained by heating the mixture of elements in the ratio 1:2:1 in a Ta crucible which was placed into an argon filled quartz ampoule. The heating schedule was 2 to 4 h at 770 K followed by 9 to 12 h at 1070 K. The resulting alloy was not single phase ScLiGe, the other phases were not identified.

### 2.1.2. *Y-Li-Ge*

No ternary phase diagram exists for the Y-Li-Ge system; however the formation of three ternary compounds has been reported by Czybulka et al. (1979), Pavlyuk et al. (1990) and Pavlyuk (1993).

YLiGe was found to adopt a ZrNiAl type with lattice parameters  $a=0.7065$ ,  $c=0.4233$  (Czybulka et al. 1979). The measured and X-ray-derived densities were  $4.56 \text{ g cm}^{-3}$  and  $4.58 \text{ g cm}^{-3}$ , respectively. The alloy was prepared by heating the elements in the stoichiometric ratio 1:2:1 in a Ta crucible under dry Ar to a temperature above 1000 K. The sample was annealed under unspecified conditions until only YLiGe and excess Li were detected by X-ray analysis. The stoichiometry was confirmed by chemical analysis (33.3 at.% Y, 32.0 at.% Li and 34.7 at.% Ge). The purity of the starting components is unstated.

$\text{Y}_4\text{LiGe}_4$  was found to adopt the  $\text{Tm}_4\text{LiGe}_4$  type ( $a=0.7144$ ,  $b=1.4799$ ,  $c=0.7757$ ; X-ray powder diffraction) by Pavlyuk et al. (1990). Samples were arc melted from the elements (Y 99.90 at.%, Li 98.2 at.%, Ge 99.999 at.%) under purified Ar at a pressure of  $1.01 \times 10^5 \text{ Pa}$  and annealed at 470 K for 240 h in a Ta container which was placed in a vacuum sealed quartz ampoule. Finally the alloy was quenched in ice-cold water.

$\text{Y}_3\text{Li}_2\text{Ge}_3$  crystallizes with  $\text{Hf}_3\text{Ni}_2\text{Si}_3$ -type structure,  $a=0.4102$ ,  $b=1.0690$ ,  $c=1.4212$  (Pavlyuk 1993; X-ray powder diffraction). The sample preparation procedure was the same as for  $\text{Y}_4\text{LiGe}_4$ .

### 2.1.3. *La-Li-Ge*

No phase diagram exists at present for the ternary La-Li-Ge system; however a series of ternary compounds have been prepared and characterized by Pavlyuk et al. (1986, 1989a).

$\text{LaLiGe}_2$  was found to crystallize with a  $\text{CaLiSi}_2$  type,  $a=0.7922$ ,  $b=0.4032$ ,  $c=1.0946$  (Pavlyuk et al. 1986; X-ray powder diffraction). Samples were arc melted from the elements (La 99.96 at.%, Li 98.2 at.%, Ge 99.999 at.%) under purified Ar at a pressure of  $1.01 \times 10^5 \text{ Pa}$  and annealed at 470 K for 240 h in Ta containers.

Pavlyuk et al. (1989a) investigated the crystal structure for  $\text{La}_2\text{Li}_2\text{Ge}_3$  ( $\text{La}_2\text{Li}_2\text{Ge}_3$  type,  $a=0.4487$ ,  $b=1.8936$ ,  $c=0.7036$ ; X-ray powder diffraction) and for  $\text{LaLi}_2\text{Ge}$  ( $\text{AlCr}_2\text{C}$  type,  $a=0.4556$ ,  $c=0.7759$ ; X-ray powder diffraction) compounds. The alloys were prepared in the same manner as  $\text{LaLiGe}_2$ .

### 2.1.4. *Ce-Li-Ge*

An isothermal section of the Ce-Li-Ge system at 470 K was reported by Pavlyuk et al. (1989a) from an X-ray powder analysis of 154 alloys (fig. 1). The samples were obtained by arc melting the elements in purified argon under a pressure of  $1.01 \times 10^5 \text{ Pa}$  and annealing at 470 K for 500 h in a Ta container. Finally the alloys were water quenched. Purity of the starting components was Ce 99.56%, Li 98.2% and Ge 99.999%. Six ternary compounds were found to exist. The immiscibility gap which exists in the Ce-Li binary system, extends in the ternary system to 17 at.% Ge.

Fig. 1. Ce–Li–Ge, isothermal section at 470 K. The dashed line indicates the liquid immiscibility gap region.

Information on the ternary phases in the Ce–Li–Ge system is due to the work of two independent groups of authors.

Schuster and Czybulka (1974) investigated the crystal structure of the  $\text{CeLi}_2\text{Ge}$  (1)<sup>1</sup> compound by means of X-ray powder and single-crystal analyses from samples which were obtained by melting of elements at 1270 K followed by long-term annealing at 1070 K and rapid quenching. The results of chemical analysis were Ce 24.6 at.%, Li 47.6 at.%, and Ge 27.8 at.%. This phase was found to adopt an orthorhombic structure with lattice parameters  $a = 1.8738$ ,  $b = 0.6926$ ,  $c = 0.4519$ . The measured density was 5.143, in agreement with the X-ray density. At variance with these data, Pavlyuk et al. (1989a) announced the  $\text{AlCr}_2\text{C}$  type for the  $\text{CeLi}_2\text{Ge}$  alloy which was arc melted and annealed at 470 K ( $a = 0.4537$ ,  $c = 0.7569$ ; X-ray powder diffraction).

Czybulka and Schuster (1979) prepared the compound  $\text{Ce}_5\text{Li}_3\text{Ge}_4$  by melting components, of unspecified purity, in the atomic ratio 1:2:1 and subsequently annealing for 24 h at 1150 K. The product contained the ternary compound together with a small amount of  $\text{Li}_{22}\text{Ge}_5$  and some unreacted Li. The excess of Li was extracted chemically. Chemical analysis gave Ce 42.7 at.%, Li 25.5 at.%, and Ge 31.8 at.%. The lattice parameters were  $a = 0.4476$ ,  $b = 1.8846$ ,  $c = 0.6947$  with a measured density of  $5.582 \text{ g cm}^{-3}$  and an X-ray density (based on space group  $\text{Cm}2\text{m}$ ) of  $5.734 \text{ g cm}^{-3}$ . Pavlyuk et al. (1988b) observed a ternary phase with almost identical lattice parameters ( $a = 0.44795$ ,  $b = 1.8846$ ,  $c = 0.69570$ ) and with the composition  $\text{Ce}_2\text{Li}_2\text{Ge}_3$  (5) (X-ray single-crystal diffraction).

The remaining four ternary compounds were prepared in the same manner as described by Pavlyuk et al. (1989a):  $\text{Ce}_2\text{LiGe}_6$  (2),  $\text{Pr}_2\text{LiGe}_6$  type,  $a = 0.4140$ ,  $b = 2.1054$ ,  $c = 0.4363$  (Pavlyuk et al. 1988b);  $\text{CeLiGe}_2$  (3),  $\text{CaLiSi}_2$  type,  $a = 0.7185$ ,  $b = 0.3965$ ,  $c = 1.0748$

<sup>1</sup> Numbers in parentheses refer to corresponding locations in figures and tables.

(Pavlyuk et al. 1986);  $\text{Ce}_2\text{LiGe}_5$  (4),  $\text{Ce}_2\text{MnGe}_5$  type,  $a=0.4360$ ,  $b=0.4197$ ,  $c=2.0711$  (Pavlyuk et al. 1989a);  $\text{Ce}_{26}\text{Li}_5\text{Ge}_{22+x}$  (6)  $x=0.37$ , own structure type,  $a=1.5402$ ,  $c=1.0900$  (Pavlyuk et al. 1987b).

### 2.1.5. Pr–Li–Ge

The isothermal section for the Pr–Li–Ge system at 470 K was established by Pavlyuk (1993) and Bodak et al. (1995) (fig. 2). For sample preparation, see Ce–Li–Ge. One ternary compound, PrLiGe, was confirmed, and five ternary phases were observed for the first time. No homogeneous ranges were encountered for the ternary compounds. The liquid immiscibility region, existing in the Pr–Li binary system, extends to 17 at.% Ge in the ternary system.

Grund et al. (1986) reported the crystal structure of the PrLiGe (6) compound: ZrNiAl type,  $a=0.7048$ ,  $c=4242$ . The sample was prepared by heating the elements (99.99 mass% Pr, 99.7 mass% Li, 99.999 mass% Ge) in the ratio 1:2:1 in a Ta crucible which was placed in an Ar-filled quartz ampoule. The heating schedule was 5–12 h at 850 K followed by 12–15 h at 1170 K. Excess Li was extracted from the product chemically. Chemical analysis confirmed the stoichiometry to be 33.2 at.% Pr, 34.5 at.% Li, and 32.3 at.% Ge.

Five other ternary compounds were observed and characterized by the Ukrainian group at L'viv University:  $\text{Pr}_2\text{LiGe}_6$  (1) belongs to a new structure type,  $a=0.41268$ ,  $b=2.10520$ ,  $c=0.43455$  (Pavlyuk et al. 1988a);  $\text{PrLi}_2\text{Ge}$  (2) adopts  $\text{AlCr}_2\text{C}$  with  $a=0.4499$ ,  $c=0.7543$  (Pavlyuk et al. 1989a);  $\text{PrLiGe}_2$  (3) is of the  $\text{CaLiSi}_2$  type,  $a=0.7813$ ,  $b=0.3948$ ,  $c=1.0695$  (Pavlyuk et al. 1986);  $\text{Pr}_2\text{LiGe}_5$  (4) crystallizes with the  $\text{Ce}_2\text{MnGe}_5$  type,  $a=0.4299$ ,  $b=0.4157$ ,  $c=2.0597$  (Pavlyuk et al. 1989a);  $\text{Pr}_2\text{Li}_2\text{Ge}_3$  (5) belongs to the

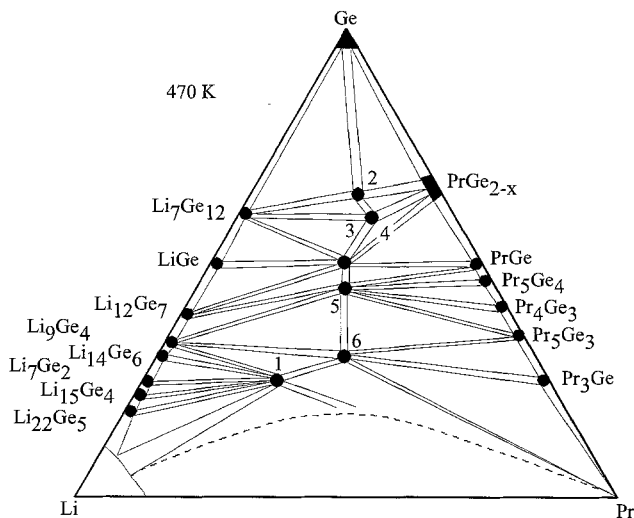

Fig. 2. Pr–Li–Ge, isothermal section at 470 K. The dashed line indicates the liquid immiscibility gap region.

$\text{Ce}_2\text{Li}_2\text{Ge}_3$  type,  $a=0.4422$ ,  $b=1.8653$ ,  $c=0.6908$  (Pavlyuk et al. 1989a). The alloys for investigations were prepared in the same manner as used for the investigation of the Pr–Li–Ge isothermal section.

### 2.1.6. Nd–Li–Ge

Pavlyuk and Bodak (1992a) were the first to investigate the phase equilibria within the Nd–Li–Ge system at 470 K over the whole concentration region by X-ray powder diffraction from the samples which were prepared in the manner indicated in the present review in the Ce–Li–Ge section. Phase relations are characterized by the existence of five ternary compounds (fig. 3). The liquid immiscibility field, originating from the Nd–Li binary system, extends to 17 at.% Ge at higher temperatures in the ternary system.

$\text{NdLiGe}$  (5) was found to crystallize with the  $\text{ZrNiAl}$  type with lattice parameters as  $a=0.7267$ ,  $c=0.4351$  by Czybulka et al. (1990) (X-ray diffraction). Results of chemical analysis confirmed the stoichiometry (33.3 at.% Nd, 34.1 at.% Li and 32.6 at.% Ge). The alloy was obtained by heating the elements in the ratio 1:2.5:1 in a Ta crucible under dry Ar for 12 h at 770 K followed by slow heating to 1100 K and holding at 1100 for 48 h.

The crystal structure of the  $\text{NdLiGe}_2$  (2) compound was investigated by Pavlyuk et al. (1986). It was found to adopt the  $\text{CaLiSi}_2$  type with lattice parameters as  $a=0.7728$ ,  $b=0.3915$ ,  $c=1.0564$ . For experimental details, see Nd–Li–Ge.

Pavlyuk et al. (1989a) prepared and characterized the compounds  $\text{NdLi}_2\text{Ge}$  (1),  $\text{AlCr}_2\text{C}$  type,  $a=0.4445$ ,  $b=0.7455$ ;  $\text{Nd}_2\text{LiGe}_5$  (3),  $\text{Ce}_2\text{MnGe}_5$  type,  $a=0.4297$ ,  $b=0.4152$ ,  $c=2.0378$ ;  $\text{Nd}_2\text{Li}_2\text{Ge}_3$  (4),  $\text{Ce}_2\text{Li}_2\text{Ge}_3$  type,  $a=0.4414$ ,  $b=1.8621$ ,  $c=0.6892$ . For sample preparation, see Nd–Li–Ge.

Fig. 3. Nd–Li–Ge, isothermal section at 470 K. The dashed line indicates the liquid immiscibility gap region.

2.1.7. *Sm–Li–Ge*

The phase-field distribution in the ternary Sm–Li–Ge system at 470 K is characterized by existence of four ternary compounds (fig. 4) (Pavlyuk 1993, Bodak et al. 1995). No homogeneous ranges were encountered for the ternary compounds. The immiscibility gap which exists in the Sm–Li binary system, extends in the ternary system to 17 at.% Ge. The alloys were synthesized by arc melting in a purified Ar atmosphere under a pressure of  $1.01 \times 10^5$  Pa using 99.89 mass% Sm, 98.2 mass% Li and 99.999 mass% Ge. The resulting buttons were annealed at 470 K for 500 h in a Ta container. Finally the alloys were water quenched.

Fig. 4. Sm–Li–Ge, isothermal section at 470 K. The dashed line indicates the liquid immiscibility gap region.

SmLiGe (4) was found to crystallize with the ZrNiAl type with a lattice parameters  $a=0.7192$ ,  $c=0.4308$  by Czybulka et al. (1990) (X-ray diffraction). Chemical analysis gave 33.5 at.% Sm, 32.3 at.% Li and 34.2 at.% Ge, confirming the stoichiometry. The alloy was obtained by heating the elements in the ratio 1:2.5:1 in a Ta crucible under dry Ar for 12 h at 770 K followed by slow heating to 1100 K and holding at 1100 K for 48 h. Pavlyuk (1989) confirmed the crystal structure and determined the lattice parameters as  $a=0.7193$ ,  $c=0.4316$ .

SmLiGe<sub>2</sub> (1) was observed to adopt the CaLiSi<sub>2</sub> type,  $a=0.7741$ ,  $b=0.3973$ ,  $c=1.0488$  (Pavlyuk et al. 1986; X-ray diffraction). For experimental details, see Sm–Li–Ge.

Pavlyuk et al. (1989a) prepared and characterized the following compounds: Sm<sub>2</sub>LiGe<sub>5</sub> (2), Ce<sub>2</sub>MnGe<sub>5</sub> type,  $a=0.4238$ ,  $b=0.4123$ ,  $c=2.0287$ ; Sm<sub>2</sub>Li<sub>2</sub>Ge<sub>3</sub> (3), Ce<sub>2</sub>Li<sub>2</sub>Ge<sub>3</sub> type,  $a=0.4394$ ,  $b=1.8537$ ,  $c=0.6860$ . For sample preparation, see Sm–Li–Ge.

### 2.1.8. *Eu–Li–Ge*

The only information available on the interaction of the components in the Eu–Li–Ge system is the formation of the  $\text{EuLiGe}_2$  compound which was observed by Pavlyuk et al. (1986). It was reported to adopt the  $\text{CaLiSi}_2$  type,  $a=0.8174$ ,  $b=0.3977$ ,  $c=1.0988$  from X-ray powder diffraction analysis. For sample preparation, see Ce–Li–Ge.

### 2.1.9. *Gd–Li–Ge*

Figure 5 represents the isothermal section of the Gd–Li–Ge system at 470 K after Pavlyuk (1989). For sample preparation, see Ce–Li–Ge. Phase relations are characterized by the existence of three ternary compounds. The liquid immiscibility gap which exists in the Gd–Li system, extends to 22 at.% Ge in the ternary system.

Czybulka et al. (1979) reported the crystallographic characteristics for the  $\text{GdLiGe}$  compound (ZrNiAl type,  $a=0.7135$ ,  $c=0.4285$ ). The measured and X-ray densities were  $6.17 \text{ g cm}^{-3}$  and  $6.23 \text{ g cm}^{-3}$ , respectively. The alloy was prepared by heating the elements in the stoichiometric ratio 1:2:1 in a Ta crucible under dry Ar to a temperature above 1000 K. The sample was annealed under unspecified conditions until only  $\text{GdLiGe}$  and excess Li were detected by X-ray analysis. The stoichiometry was confirmed by chemical analysis (34.0 at.% Gd, 33.2 at.% Li and 32.8 at.% Ge).

$\text{GdLiGe}_2$  and  $\text{Gd}_4\text{LiGe}_4$  were found to adopt the  $\text{CaLiSi}_2$  type ( $a=0.7784$ ,  $b=0.3867$ ,  $c=1.0416$ ; X-ray powder diffraction) by Pavlyuk (1989) and the  $\text{Tm}_4\text{LiGe}_4$  type ( $a=0.7159$ ,  $b=1.4749$ ,  $c=0.7713$ ; X-ray powder diffraction) by Pavlyuk et al. (1990), respectively. For sample preparation, see Gd–Li–Ge.

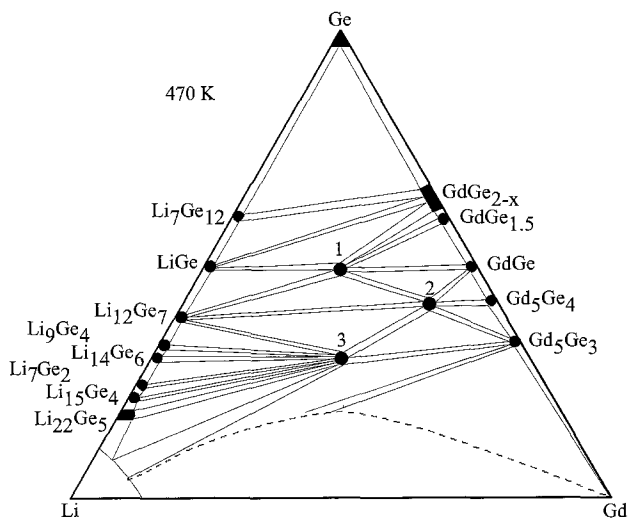

Fig. 5. Gd–Li–Ge, isothermal section at 470 K. The dashed line indicates the liquid immiscibility gap region.

### 2.1.10. *Tb–Li–Ge*

Information on the interaction of terbium with lithium and germanium is due to the work of two groups of authors: Grund et al. (1986) and Pavlyuk (1993).

Grund et al. (1986) investigated the crystal structure of TbLiGe. The structure type was established as ZrNiAl with lattice parameters  $a=0.7083$ ,  $c=0.4257$  from X-ray powder diffraction analysis. The measured density was  $6.44\text{ g cm}^{-3}$  and the X-ray density  $6.42\text{ g cm}^{-3}$ . The sample was prepared by heating the elements (99.99 mass% Tb, 99.7 mass% Li, 99.999 mass% Ge) in the ratio 1:2:1 in a Ta crucible which was placed in an Ar-filled quartz ampoule. The heating schedule was 5–12 h at 850 K followed by 12–15 h at 1170 K. Excess Li was extracted from the product chemically. Chemical analysis confirmed the stoichiometry to be 32.5 at.% Tb, 34.1 at.% Li and 33.4 at.% Ge.

Two more compounds were observed and characterized by Pavlyuk (1993): Tb<sub>4</sub>LiGe<sub>4</sub> with the Tm<sub>4</sub>LiGe<sub>4</sub> type,  $a=0.7079$ ,  $b=1.4682$ ,  $c=0.7699$  (X-ray powder diffraction) and Tb<sub>3</sub>Li<sub>2</sub>Ge<sub>3</sub> with the Hf<sub>3</sub>Ni<sub>2</sub>Si<sub>3</sub> type,  $a=0.4107$ ,  $b=1.0740$ ,  $c=1.4198$  (X-ray powder diffraction). For experimental details, see Ce–Li–Ge.

### 2.1.11. *Dy–Li–Ge*

Little information exists on the Dy–Li–Ge system, however three ternary compounds were found and characterized.

Grund et al. (1986) reported the crystal structure of the DyLiGe compound: ZrNiAl type,  $a=0.7048$ ,  $c=0.4242$ . The measured density was  $6.46\text{ g cm}^{-3}$  and the X-ray density  $6.61\text{ g cm}^{-3}$ . Results of chemical analysis confirmed the stoichiometry to be 33.2 at.% Dy, 34.5 at.% Li and 32.3 at.% Ge. For sample preparation, see Tb–Li–Ge.

Two more compounds were observed and characterized by Pavlyuk (1993): Dy<sub>4</sub>LiGe<sub>4</sub> with the Tm<sub>4</sub>LiGe<sub>4</sub> type,  $a=0.7064$ ,  $b=1.4654$ ,  $c=0.7681$  (X-ray powder diffraction) and Dy<sub>3</sub>Li<sub>2</sub>Ge<sub>3</sub> with the Hf<sub>3</sub>Ni<sub>2</sub>Si<sub>3</sub> type,  $a=0.4097$ ,  $b=1.0602$ ,  $c=1.4121$  (X-ray powder diffraction). For experimental details, see Ce–Li–Ge.

### 2.1.12. *Ho–Li–Ge*

Phase relations have been established for the ternary Ho–Li–Ge system at 470 K by Pavlyuk (1993) (fig. 6); seven ternary compounds have been observed and characterized. The immiscibility gap which exists in the Ho–Li binary system, extends in the ternary system to 17 at.% Ge. For experimental details, see Ce–Li–Ge.

From the preliminary investigation of the interaction of holmium with lithium and germanium, HoLiGe was found to crystallize with ZrNiAl type with lattice parameters  $a=0.7036$ ,  $c=0.4241$  by Czybulka et al. (1990) (X-ray diffraction). Chemical analysis gave 33.4 at.% Ho, 34.2 at.% Li and 32.4 at.% Ge. The alloy was obtained by heating the elements in the ratio 1:2.5:1 in a Ta crucible under dry Ar for 12 h at 770 K followed by slow heating to 1100 K and holding at 1100 K for 48 h.

Investigating the phase equilibria in the ternary Ho–Li–Ge system, Pavlyuk (1993) observed and characterized three ternary compounds: Ho<sub>4</sub>LiGe<sub>4</sub> was found to adopt a Tm<sub>4</sub>LiGe<sub>4</sub> type,  $a=0.7039$ ,  $b=1.4649$ ,  $c=0.7674$  (X-ray powder diffraction); Ho<sub>3</sub>Li<sub>2</sub>Ge<sub>3</sub>

Fig. 6. Ho–Li–Ge, isothermal section at 470 K. The dashed line indicates the liquid immiscibility gap region.

was reported to crystallize with the  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  type,  $a=0.4003$ ,  $b=1.0509$ ,  $c=1.4097$  (X-ray powder diffraction);  $\text{TmLi}_{1-x}\text{Ge}_2$  type was announced for the  $\text{HoLi}_{1-x}\text{Ge}_2$  compound,  $a=0.4017$ ,  $b=0.8126$ ,  $c=0.3881$ ,  $\gamma=104.24^\circ$ . Three more ternary compounds with an unknown structure were observed by Pavlyuk (1993),  $\text{HoLi}_6\text{Ge}_3$ ,  $\text{HoLi}_4\text{Ge}_5$  and  $\text{Ho}_2\text{Li}_5\text{Ge}_3$ . For experimental details, see Ce–Li–Ge.

### 2.1.13. Er–Li–Ge

A partial isothermal section for the Er–Li–Ge system was constructed by Pavlyuk (1993); four ternary compounds were found to exist (fig. 7). For sample preparation, see Ce–Li–Ge.

$\text{ErLiGe}$  (2) was found to crystallize with a  $\text{ZrNiAl}$  type with lattice parameters  $a=0.7005$ ,  $c=0.4214$  (Pavlyuk 1989; Pavlyuk et al. 1991a) from X-ray powder diffraction of arc melted in a purified Ar atmosphere under a pressure of  $1.01 \times 10^5$  Pa samples which were annealed in Ta containers at 470 K for 240 h. Purity of the starting components was 99.82 mass% Er, 98.2 mass% Li and 99.999 mass% Ge. Czybulka et al. (1990) confirmed the crystal structure for the compound of equiatomic composition,  $\text{ZrNiAl}$  type,  $a=0.6985$ ,  $c=0.4219$  (X-ray single-crystal data). Chemical analysis gave 33.6 at.% Er, 32.4 at.% Li and 34.0 at.% Ge. For sample preparation, see Ho–Li–Ge.

Pavlyuk et al. (1990) reported on the crystal structure investigation for the  $\text{Er}_4\text{LiGe}_4$  (4) compound,  $\text{Tm}_4\text{LiGe}_4$  type,  $a=0.7031$ ,  $b=1.4555$ ,  $c=0.7664$  (X-ray powder diffraction). For sample preparation, see Er–Li–Ge system after Pavlyuk (1989) and Pavlyuk et al. (1991a).

Two more ternary compounds were observed and characterized by Pavlyuk (1993):  $\text{Er}_3\text{Li}_2\text{Ge}_3$  (3) was reported to crystallize with the  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  type,  $a=0.4001$ ,  $b=$

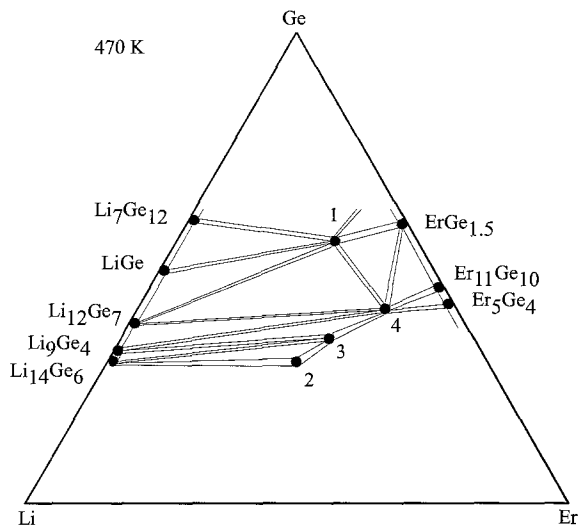

Fig. 7. Er–Li–Ge, partial isothermal section at 470 K (30–70 at.% Ge).

1.0498,  $c=1.4091$  (X-ray powder diffraction);  $\text{TmLi}_{1-x}\text{Ge}_2$  type was announced for the  $\text{ErLi}_{1-x}\text{Ge}_2$  (1) compound,  $a=0.4007$ ,  $b=0.8101$ ,  $c=0.3876$ ,  $\gamma=104.24^\circ$ . For experimental details, see Er–Li–Ge after Pavlyuk (1989) and Pavlyuk et al. (1991a).

2.1.14. *Tm–Li–Ge*

The phase diagram for the Tm–Li–Ge system was constructed by Pavlyuk (1989) (fig. 8). Phase relations are characterized by existence of four ternary compounds. No

Fig. 8. Tm–Li–Ge, isothermal section at 470 K. The dashed line indicates the liquid immiscibility gap region.

homogeneity regions were observed for the ternary phases. The liquid immiscibility gap which originates from the Tm–Li binary system, stretches to 23 at.% Ge in the ternary system. For sample preparation, see Ce–Li–Ge system.

The crystal structure for four ternary compounds was established by the Ukrainian group at L'viv University:  $\text{TmLi}_{1-x}\text{Ge}_2$  (1) crystallizes with its own structure type,  $a = 0.4008$ ,  $b = 0.8123$ ,  $c = 0.3875$ ,  $\gamma = 104.24^\circ$  (Pavlyuk et al. 1991b; X-ray single-crystal data);  $\text{TmLiGe}$  (2) belongs to the  $\text{ZrNiAl}$  type,  $a = 0.6917$ ,  $c = 0.4813$  (Pavlyuk et al. 1991a; X-ray powder diffraction);  $\text{Tm}_3\text{Li}_2\text{Ge}_3$  (3) adopts the  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  type,  $a = 0.3990$ ,  $b = 1.0506$ ,  $c = 1.4090$  (Pavlyuk and Bodak 1992b);  $\text{Tm}_4\text{LiGe}_4$  (4) represents a new type of structure,  $a = 0.7013$ ,  $b = 1.4429$ ,  $c = 0.7524$  (Pavlyuk et al. 1990; X-ray single-crystal diffraction data). For experimental details, see Ce–Li–Ge.

#### 2.1.15. *Yb–Li–Ge*

The phase-field distribution in the ternary Yb–Li–Ge system at 470 K is characterized by existence of four ternary compounds (fig. 9) (Pavlyuk 1993 and Bodak et al. 1995). No homogeneous ranges were encountered for the ternary compounds. The immiscibility gap which exists in the Yb–Li binary system, extends in the ternary system to 17 at.% Ge. The alloys were synthesized by arc melting in a purified Ar atmosphere under a pressure of  $1.01 \times 10^5$  Pa. The resulting buttons were annealed at 470 K for 500 h in a Ta container which were placed in the evacuated vacuum sealed quartz tube. Finally the alloys were quenched in ice cold water. The purity of the starting materials was Yb 99.82 mass%, Li 98.2 mass% and Ge 99.999 mass%.

Grund et al. (1986) reported the crystal structure of the  $\text{YbLiGe}$  (1) compound:  $\text{ZrNiAl}$  type,  $a = 0.6939$ ,  $c = 4183$ . The measured density was  $7.18 \text{ g cm}^{-3}$  and the X-ray density  $7.21 \text{ g cm}^{-3}$ . Results of chemical analysis confirmed the stoichiometry and gave

Fig. 9. Yb–Li–Ge, partial isothermal section at 470 K (30–70 at.% Ge).

33.6 at.% Yb, 33.2 at.% Li and 33.2 at.% Ge. For sample preparation, see Tb–Li–Ge. The crystal structure was confirmed by Pavlyuk (1993) and Bodak et al. (1995):  $a=0.6944$ ,  $c=0.4190$ .

The results of X-ray single-crystal investigation for three other compounds are the following:  $\text{Yb}_8\text{LiGe}_{13}$  (2) belongs to a new structure type,  $a=1.1317$ ,  $b=1.5577$ ,  $c=1.0817$ ,  $\gamma=106.24^\circ$  (Pavlyuk et al. 1987a);  $\text{Yb}_5\text{Li}_4\text{Ge}_4$  (3) crystallizes with the  $\text{Nb}_5\text{Cu}_4\text{Si}_4$  type,  $a=1.1210$ ,  $c=0.43698$  (Pavlyuk et al. 1989b);  $\text{Yb}_4\text{LiGe}_4$  (4) adopts the  $\text{Tm}_4\text{LiGe}_4$  type,  $a=0.701$ ,  $b=1.441$ ,  $c=0.753$  (Pavlyuk et al. 1990). The samples were prepared in the same manner as the alloys for the investigations of the Yb–Li–Ge phase diagram.

#### 2.1.16. Lu–Li–Ge

The phase diagram for the Lu–Li–Ge system was constructed by Pavlyuk (1993) (fig. 10). The phase relations are characterized by existence of four ternary compounds. No homogeneity regions were observed for the ternary phases. The liquid immiscibility gap which originates from the Lu–Li binary system, stretches to 23 at.% Ge in the ternary system. For sample preparation, see Ce–Li–Ge.

The crystal structure for four ternary compounds was established by the Ukrainian group at L'viv University:  $\text{LuLi}_{1-x}\text{Ge}_2$  (1) crystallizes with the  $\text{TmLi}_{1-x}\text{Ge}_2$  structure type,  $a=0.3988$ ,  $b=0.8019$ ,  $c=0.3867$ ,  $\gamma=104.2^\circ$  (Pavlyuk et al. 1991b; X-ray powder diffraction);  $\text{LuLiGe}$  (2) belongs to the  $\text{ZrNiAl}$  type,  $a=0.6933$ ,  $c=0.4200$  (Pavlyuk et al. 1991a; X-ray powder diffraction);  $\text{Lu}_3\text{Li}_2\text{Ge}_3$  (3) adopts the  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  type,  $a=0.3959$ ,  $b=1.0475$ ,  $c=1.4051$  (Pavlyuk and Bodak 1992b);  $\text{Lu}_4\text{LiGe}_4$  (4) has the  $\text{Tm}_4\text{LiGe}_4$  type of structure,  $a=0.7000$ ,  $b=1.4322$ ,  $c=0.7524$  (Pavlyuk et al. 1990; X-ray powder diffraction data). For experimental details, see Ce–Li–Ge.

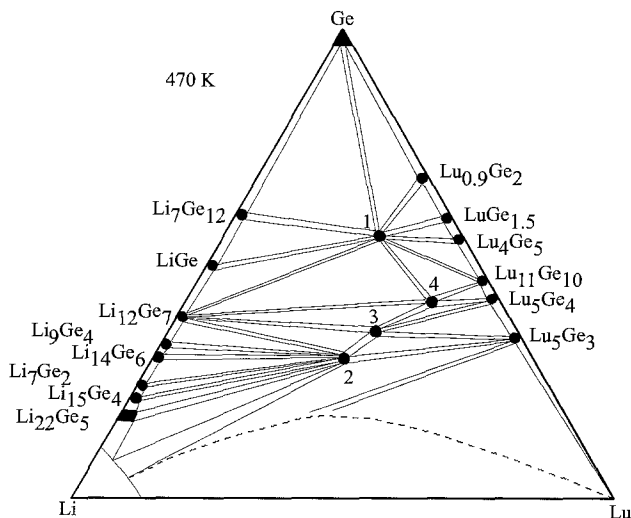

Fig. 10. Lu–Li–Ge, isothermal section at 470 K. The dashed line indicates the liquid immiscibility gap region.

## 2.2. R–Mg–Ge systems

### 2.2.1. Eu–Mg–Ge

The information on the interaction of the components in the Eu–Mg–Ge system is due to Zmii et al. (1973) and Merlo et al. (1993).

Zmii et al. (1973) investigated the crystal structures of  $\text{EuMg}_3\text{Ge}_3$  compound (own structure type,  $a=0.4485$ ,  $b=3.060$ ,  $c=0.4485$ ; X-ray single-crystal diffraction).

Merlo et al. (1993) synthesized  $\text{EuMgGe}$  compound and established its crystal structure as the  $\text{TiNiSi}$  type,  $a=0.7756$ ,  $b=0.4580$ ,  $c=0.8444$  from X-ray powder diffraction. The alloy was obtained from metals with a purity of 99% for europium, and 99.999% for magnesium and germanium. The proper amounts of constituent elements were placed in sealed tantalum crucibles, which were arc welded under argon, melted in an induction furnace and annealed for 1 month at 870 K.

### 2.2.2. Yb–Mg–Ge

Merlo et al. (1993) investigated the crystal structure of  $\text{YbMgGe}$  compound by the X-ray single-crystal method. It was found to adopt the  $\text{TiNiSi}$  type,  $a=0.7474$ ,  $b=0.4436$ ,  $c=0.8343$ . The sample was synthesized in the same manner as  $\text{EuMgGe}$ .

## 3. Rare-earth–p element–germanium systems

### 3.1. R–B–Ge systems

#### 3.1.1. Y–B–Ge

The isothermal section of the Y–B–Ge system at 1070 K (fig. 11) was investigated by Marko et al. (1978) using X-ray powder analysis of samples prepared by arc melting solid pieces of yttrium and germanium with compacted powder of boron. The melted buttons were then annealed in evacuated quartz tubes at 1070 K. No ternary compounds were observed.

#### 3.1.2. La–B–Ge

An early investigation of the La–B–Ge system reported on the existence of solid solution of boron in the binary  $\text{La}_5\text{Ge}_3$  compound which was observed by X-ray methods (Mayer and Felner 1974). Samples were obtained by heating of mixture of starting components up to 1870 K in the He atmosphere in tantalum crucibles. The phase relations in the complete isothermal section at 970 K have been determined by Marko et al. (1978). For sample preparation, see Y–B–Ge. Phase relations are characterized by the absence of ternary compounds (fig. 12). No solubility of boron in the  $\text{La}_5\text{Ge}_3$  compound has been observed.

Fig. 11. Y–B–Ge, isothermal section at 1070 K.

Fig. 12. La–B–Ge, isothermal section at 970 K.

### 3.1.3. Ce–B–Ge

Phase relations in the isothermal section at 870 K have been determined by Marko and Kuz'ma (1979) from X-ray powder diffraction analysis (fig. 13). For sample preparation, see Y–B–Ge. No ternary compounds have been found. Mutual solid solubilities of the binary compounds were found to be negligible.

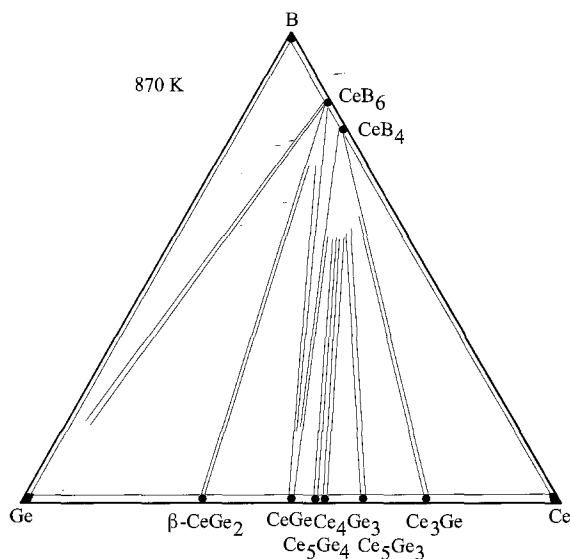

Fig. 13. Ce-B-Ge, isothermal section at 870 K.

#### 3.1.4. *Nd-B-Ge*

No phase diagram exists for the Nd-B-Ge system, however the solubility of boron in the  $\text{Nd}_5\text{Ge}_3$  compound has been studied by means of X-ray diffraction (Mayer and Felner 1974). The limits of solid solution have not been reported. Samples were obtained by heating of mixture of starting components up to 1870 K in the He atmosphere in Ta crucibles.

#### 3.1.5. *Gd-B-Ge*

The only information on the Gd-B-Ge system is due to Mayer and Felner (1974) who investigated the solubility of boron in the  $\text{Gd}_5\text{Ge}_3$  compound by means of X-ray diffraction. The limits of solid solution have not been indicated. For sample preparation, see La-B-Ge.

#### 3.1.6. *Tb-B-Ge*

No ternary phase diagram exists for the Tb-B-Ge system; however the formation of a solid solution originating at the binary  $\text{Tb}_5\text{Ge}_3$  compound has been observed (Mayer and Felner 1974). The maximum concentration of boron in  $\text{Tb}_5\text{Ge}_3$  has not been shown. For experimental details, see La-B-Ge.

#### 3.1.7. *Dy-B-Ge*

Solubility of boron in the  $\text{Dy}_5\text{Ge}_3$  compound has been studied by X-ray methods (Mayer and Felner 1974). For experimental details, see La-B-Ge.

### 3.2. R–Al–Ge systems

#### 3.2.1. Sc–Al–Ge

No phase diagram exists for the Sc–Al–Ge system, however the formation of  $\text{Sc}_{11}\text{Al}_2\text{Ge}_8$  compound has been reported by Zhao et al. (1991). It was found to crystallize with a new ordered variant of the  $\text{Ho}_{11}\text{Ge}_{10}$  type with Al atoms substituting for Ge atoms on one crystallographic site. The lattice parameters are  $a=1.0419$ ,  $c=1.4974$ . A single crystal was isolated from a sample which was arc melted in an argon atmosphere. Purity of starting components was 99.99 mass% for Sc, Al and Ge.

The same group of authors observed and characterized the  $\text{ScAlGe}$  compound,  $\text{YAlGe}$  type,  $a=0.3934$ ,  $b=0.9928$ ,  $c=0.5519$  (Zhao and Parthé 1990; X-ray powder diffraction).

#### 3.2.2. Y–Al–Ge

Figure 14 represents the partial isothermal section of the Y–Al–Ge system at 770 K after Muravyeva et al. (1971). Three ternary compounds were found to exist from X-ray phase analysis of alloys prepared by arc melting the proper amounts of pure components in an argon atmosphere. The resulting buttons were annealed for two weeks at 770 K and finally quenched in ice-cold water. Purity of starting components was greater than 99.9 mass%.

Muravyeva et al. (1971) reported on the crystal structure investigation for the  $\text{YAl}_{1.7-2.2}\text{Ge}_{2.3-1.8}$  (1) ( $\text{CaAl}_2\text{Si}_2$  type,  $a=0.4196-0.4196$ ,  $b=0.6702-0.6775$ ; X-ray powder diffraction).

The  $\text{YAl}_{0.9-1.3}\text{Ge}_{1.1-0.7}$  compound (3) was claimed by Yanson (1975) to adopt the  $\text{DyAlGe}$  type ( $\text{Cmc}_2$  space group) at the equiatomic composition with lattice parameters  $a=0.4200$ ,  $b=1.062$ ,  $c=0.5908$  (X-ray powder diffraction data). At variance with these data, Zhao and Parthé (1990) announced the  $\text{YAlGe}$  type with  $\text{Cmcm}$  space

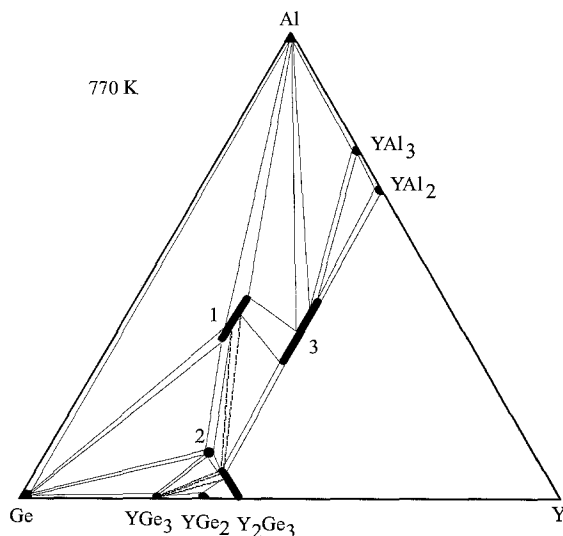

Fig. 14. Y–Al–Ge, partial isothermal section at 770 K (0–33 at.% Y).

group and lattice parameters  $a=0.40504$ ,  $b=1.04440$ ,  $c=0.57646$  (X-ray single-crystal diffraction).

$Y_3AlGe_6$  (2) has a hexagonal lattice with unknown unit cell dimensions (Yanson 1975).

### 3.2.3. La–Al–Ge

Phase equilibria in the partial isothermal section (0–33 at.% La) at 770 K have been derived by Muravyeva and Zarechnyuk (1970) by means of X-ray powder diffraction of alloys, as shown in fig. 15. For sample preparation, see Y–Al–Ge. Five ternary compounds were found to exist.  $LaGe_2$  dissolves 13 at.% Al.

The formation of two ternary compounds was reported in the early investigations performed by Raman and Steinfink (1967):  $LaAl_{1.5-1.8}Ge_{0.5-0.2}$  (5) with  $AlB_2$  type,  $a=0.435-0.440$ ,  $c=0.442-0.440$  and  $LaAlGe$  (4),  $\alpha-ThSi_2$  type,  $a=0.4307$ ,  $c=1.472$ . The structure of the latter phase has been confirmed by Zhao and Parthé (1990),  $a=0.4341$ ,  $c=1.4784$  (X-ray powder diffraction). The alloy was prepared by arc melting under an argon atmosphere followed by annealing at 873 K for 100 h.

Muravyeva et al. (1971) observed the  $CaAl_2Si_2$  type for the  $LaAl_2Ge_2$  compound (2) ( $a=0.428$ ,  $c=0.700$ ; X-ray powder diffraction).

Two more ternary compounds which had been indicated as  $\sim LaAlGe_3$  (1) and  $\sim LaAl_{0.8-1}Ge_{2.2-2}$  (3) by Muravyeva and Zarechnyuk (1970) in the course of investigation of the isothermal section, have been characterized by the researchers from Geneva University.  $La_2Al_{1+x}Ge_{6-x}$  ( $x=0.60$ ) is a new structure type which is a vacancy variant of the orthorhombic  $SmNiGe_3$  structure,  $a=0.8373$ ,  $b=0.8833$ ,  $c=1.0887$ ,  $\beta=101.34^\circ$  (Zhao and Parthé 1991a; X-ray single-crystal diffraction data).  $La_2Al_3Ge_4$  was announced to crystallize with the  $Ba_2Cd_3Bi_4$  type,  $a=0.6146$ ,  $b=1.5194$ ,  $c=0.8037$  (X-ray single-

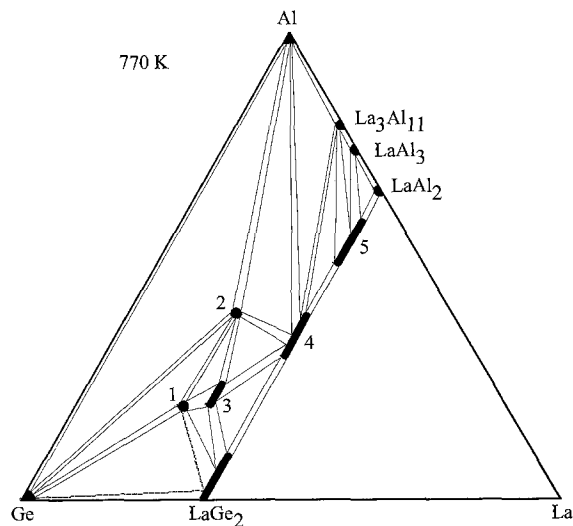

Fig. 15. La–Al–Ge, partial isothermal section at 770 K (0–33 at.% La).

crystal diffraction, Zhao and Parthé 1991b). Single crystals were isolated from samples obtained by arc melting the proper amounts of pure components in an argon atmosphere (La, Al and Ge: 99.99 mass%). The weight losses were 0.4% and 0.5% for  $\text{La}_2\text{Al}_{1+x}\text{Ge}_{6-x}$  ( $x = 0.60$ ) and  $\text{La}_2\text{Al}_3\text{Ge}_4$ , respectively. The alloys were annealed at 770 K for two months in an Ar-filled silica tube.

### 3.2.4. Ce–Al–Ge

The isothermal section of the Ce–Al–Ge system at 770 K (0–33 at.% Ce) was reported by Muravyeva and Zarechnyuk (1970) from an X-ray powder analysis of alloys prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the alloys were quenched in water. The purity of the starting components was greater than 99.9 mass%. Five ternary compounds were found to exist (fig. 16). For all of them except  $\text{CeAl}_2\text{Ge}_2$ , the formation of homogeneity regions was observed.

Information on the ternary phases in the Ce–Al–Ge system is due to the work of three independent groups of authors.

The formation of one ternary compound was reported in an early investigation performed by Raman and Steinfink (1967):  $\text{CeAl}_{0.5-0.6}\text{Ge}_{0.5-0.4}$  (5) with the  $\text{AlB}_2$  type,  $a = 0.433-0.436$ ,  $c = 0.432-0.429$ .

Muravyeva and Zarechnyuk (1970) observed the  $\text{CaAl}_2\text{Si}_2$  type for the  $\text{CeAl}_2\text{Ge}_2$  compound (2) ( $a = 0.427$ ,  $c = 0.695$ ; X-ray powder diffraction). For sample preparation, see above.

Three more ternary compounds which had earlier been indicated as  $\sim\text{CeAl}_{0.5-0.8}\text{Ge}_{3.5-3.2}$  (1),  $\sim\text{CeAl}_{0.8-1}\text{Ge}_{2.2-2}$  (3) and  $\text{CeAl}_{0.7-1.2}\text{Ge}_{1.3-0.8}$  (4) by Muravyeva and Zarechnyuk (1970) during the investigation of the isothermal section, have been characterized by the group of authors from Geneva University.  $\text{Ce}_2\text{Al}_{1+x}\text{Ge}_{6-x}$  (1) was found to adopt the

Fig. 16. Ce–Al–Ge, partial isothermal section at 770 K. (0–33 at.% Ce).

$\text{La}_2\text{Al}_{1+x}\text{Ge}_{6-x}$ -type structure,  $a=0.8292$ ,  $b=0.8691$ ,  $c=1.0739$ ,  $\beta=101.15^\circ$  (Zhao and Parthé 1991a; X-ray powder diffraction data).  $\text{Ce}_2\text{Al}_3\text{Ge}_4$  (3) was announced to crystallize with the  $\text{Ba}_2\text{Cd}_3\text{Bi}_4$  type,  $a=0.60935$ ,  $b=1.5061$ ,  $c=0.7974$  (X-ray powder diffraction; Zhao and Parthé 1991b).  $\alpha\text{-ThSi}_2$ -type structure was observed for the  $\text{CeAlGe}$  (4) compound,  $a=0.42889$ ,  $c=1.4721$  (X-ray powder diffraction, Zhao and Parthé 1990). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Ce, Al and Ge: 99.99 mass%). The alloys were annealed at 770 K for two months in an Ar-filled silica tube.

### 3.2.5. Pr–Al–Ge

No phase diagram is available for the ternary Pr–Al–Ge system, however information on the formation and crystal structure of four compounds exists due to the work of the Ukrainian scientific group from Lviv University as well as of the group of authors from Geneva University.

$\text{PrAlGe}$  belongs to the  $\alpha\text{-ThSi}_2$  type,  $a=0.4273$ ,  $c=1.463$  (Ryabokon' 1974; X-ray powder diffraction). Zhao and Parthé (1990) confirmed the structure for the equiatomic compound,  $a=0.42642$ ,  $b=1.4685$  (X-ray powder diffraction). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Pr, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for 100 h in a silica tube.

Zarechnyuk et al. (1970) observed the  $\text{CaAl}_2\text{Si}_2$  type for the  $\text{PrAl}_2\text{Ge}_2$  compound ( $a=0.4264$ ,  $c=0.6896$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

Two more ternary compounds have been observed and characterized by Zhao and Parthé (1991a,b).  $\text{Pr}_2\text{Al}_{1+x}\text{Ge}_{6-x}$  was found to adopt the  $\text{La}_2\text{Al}_{1+x}\text{Ge}_{6-x}$  type structure,  $a=0.8244$ ,  $b=0.8630$ ,  $c=1.0711$ ,  $\beta=101.09^\circ$  (Zhao and Parthé 1991a; X-ray powder diffraction data).  $\text{Pr}_2\text{Al}_3\text{Ge}_4$  (3) was announced to crystallize with the  $\text{Ba}_2\text{Cd}_3\text{Bi}_4$  type,  $a=0.6056$ ,  $b=1.5000$ ,  $c=0.7920$  (X-ray powder diffraction, Zhao and Parthé 1991b). In both cases samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Pr, Al and Ge: 99.99 mass%). The alloys were annealed at 770 K for two months in an Ar-filled silica tubes.

### 3.2.6. Nd–Al–Ge

No phase diagram is available yet for the ternary Nd–Al–Ge system, however information on the existence and crystal structure of five compounds exists due to the work of different scientific groups.

The formation of the  $\text{NdAl}_{1.0-1.25}\text{Ge}_{1.0-0.75}$  compounds was reported in an early investigation performed by Raman and Steinfink (1967):  $\text{AlB}_2$  type,  $a=0.4298\text{--}0.4308$ ,  $c=0.4210\text{--}0.4204$ .

$\text{NdAlGe}$  belongs to the  $\alpha\text{-ThSi}_2$  type,  $a=0.4272$ ,  $c=1.466$  (Ryabokon' 1974; X-ray powder diffraction). Zhao and Parthé (1990) confirmed the structure for the equiatomic compound,  $a=0.4233$ ,  $b=1.4638$  (X-ray powder diffraction). Samples were obtained by

arc melting the proper amounts of pure components in an argon atmosphere (Nd, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for 100 h in a silica tube.

Zarechnyuk et al. (1970) observed the  $\text{CaAl}_2\text{Si}_2$  type for the  $\text{NdAl}_2\text{Ge}_2$  compound ( $a = 0.4265$ ,  $c = 0.6827$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

$\text{Nd}_2\text{Al}_{1+x}\text{Ge}_{6-x}$  was found to adopt the  $\text{La}_2\text{Al}_{1+x}\text{Ge}_{6-x}$ -type structure,  $a = 0.8220$ ,  $b = 0.8623$ ,  $c = 1.0671$ ,  $\beta = 101.05^\circ$  (Zhao and Parthé 1991a; X-ray powder diffraction data). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Nd, Al and Ge: 99.99 mass%). The alloys were annealed at 770 K for two months in an Ar-filled silica tube.

$\text{Nd}_2\text{Al}_3\text{Ge}_4$  was announced to crystallize with the  $\text{Ba}_2\text{Cd}_3\text{Bi}_4$  type,  $a = 0.6042$ ,  $b = 1.4965$ ,  $c = 0.7897$  (X-ray powder diffraction, Zhao and Parthé 1991b). The sample was obtained in the same manner as indicated for the  $\text{Nd}_2\text{Al}_{1+x}\text{Ge}_{6-x}$  compound.

### 3.2.7. *Sm–Al–Ge*

No phase diagram has been derived yet for the ternary Sm–Al–Ge system, however information on the formation and crystal structure of four compounds exists due to the work of scientific groups from Lviv University and Geneva University.

$\text{SmAlGe}$  belongs to the  $\alpha\text{-ThSi}_2$  type,  $a = 0.4188$ ,  $c = 1.452$  (Ryabokon' 1974; X-ray powder diffraction). Zhao and Parthé (1990) confirmed the structure for the equiatomic compound,  $a = 0.41957$ ,  $b = 1.4588$  (X-ray powder diffraction). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Sm, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for 100 h in a silica tube.

Zarechnyuk et al. (1970) observed the  $\text{CaAl}_2\text{Si}_2$  type for the  $\text{PrAl}_2\text{Ge}_2$  compound ( $a = 0.4233$ ,  $c = 0.6805$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

Two more ternary compounds have been observed and investigated by the group of authors from Geneva University.  $\text{Sm}_2\text{Al}_{1+x}\text{Ge}_{6-x}$  was found to adopt the  $\text{La}_2\text{Al}_{1+x}\text{Ge}_{6-x}$ -type structure,  $a = 0.8105$ ,  $b = 0.8458$ ,  $c = 1.0613$ ,  $\beta = 101.00^\circ$  (Zhao and Parthé 1991a; X-ray powder diffraction data).  $\text{Sm}_2\text{Al}_3\text{Ge}_4$  was announced to crystallize with the  $\text{Ba}_2\text{Cd}_3\text{Bi}_4$  type,  $a = 0.6007$ ,  $b = 1.4921$ ,  $c = 0.7820$  (X-ray powder diffraction, Zhao and Parthé 1991b). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Sm, Al and Ge: 99.99 mass%). The alloys were annealed at 770 K for two months in an Ar-filled silica tube.

### 3.2.8. *Eu–Al–Ge*

Little information exists on the interaction of components in the ternary Eu–Al–Ge system. Two ternary compounds were observed and characterized.

Zarechnyuk et al. (1970) observed the  $\text{CaAl}_2\text{Si}_2$  type for the  $\text{EuAl}_2\text{Ge}_2$  compound ( $a = 0.422$ ,  $c = 0.731$ ; X-ray powder diffraction). The alloy was prepared by arc melting the

elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

The  $\alpha$ -ThSi<sub>2</sub> type was indicated for the EuAlGe compound,  $a=0.42000$ ,  $c=1.4604$  (X-ray powder diffraction, Zhao and Parthé 1990). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Eu, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for two months in a silica tube.

### 3.2.9. Gd–Al–Ge

Figure 17 represents the partial isothermal section of the Gd–Al–Ge system at 770 K after Zarechnyuk et al. (1981) from X-ray powder phase analysis of samples which were arc melted and annealed in evacuated quartz tubes for two weeks. Three ternary compounds were found to exist.

Zarechnyuk et al. (1970) observed the CaAl<sub>2</sub>Si<sub>2</sub> type for the GdAl<sub>2</sub>Ge<sub>2</sub> (1) compound ( $a=0.4248$ ,  $c=0.6714$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

GdAlGe (3) was found to crystallize with the  $\alpha$ -ThSi<sub>2</sub> type,  $a=0.4152$ ,  $c=1.4421$  (Ryabokon' 1974; X-ray powder diffraction). The sample was arc melted and annealed at 770 K. Contrary to these data, Zhao and Parthé (1990) found two types of structure for the equiatomic composition: a compound with the  $\alpha$ -ThSi<sub>2</sub> type was found to exist above 1300 K ( $a=0.41521$ ,  $c=1.4415$ ; X-ray powder diffraction), and YAlGe-type was realized below 1300 K ( $a=0.4063$ ,  $b=1.0513$ ,  $c=0.5801$ ). The phase transition temperature was determined from thermal differential analysis. Samples were obtained by arc melting

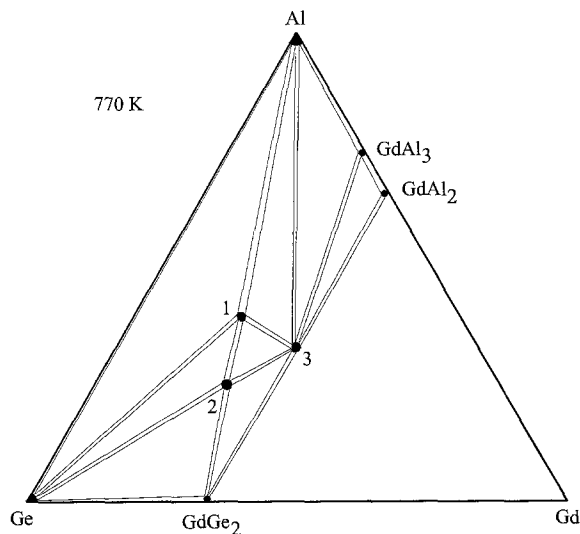

Fig. 17. Gd–Al–Ge, partial isothermal section at 770 K (0–33 at.% Gd).

the proper amounts of pure components in an argon atmosphere (Gd, Al and Ge: 99.99 mass%).

At variance with the phase diagram proposed by Zarechnyuk et al. (1981), two more compounds have been characterized by the scientific group from Geneva University.  $\text{Gd}_2\text{Al}_{1+x}\text{Ge}_{6-x}$  was found to adopt the  $\text{La}_2\text{Al}_{1+x}\text{Ge}_{6-x}$ -type structure,  $a=0.8041$ ,  $b=0.8351$ ,  $c=1.0546$ ,  $\beta=100.81^\circ$  (Zhao and Parthé 1991a; X-ray powder diffraction data).  $\text{Gd}_2\text{Al}_3\text{Ge}_4$  was announced to crystallize with the  $\text{Ba}_2\text{Cd}_3\text{Bi}_4$  type,  $a=0.5948$ ,  $b=1.4875$ ,  $c=0.7762$  (X-ray powder diffraction, Zhao and Parthé 1991b). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Gd, Al and Ge: 99.99 mass%). The alloys were annealed at 770 K for two months in an Ar-filled silica tube. These two phases are not shown in the 770 K isothermal section, fig. 17.

### 3.2.10. *Tb–Al–Ge*

No phase diagram has been derived yet for the ternary Tb–Al–Ge system, however information on the investigation of the crystal structure of three compounds exists due to the work of different scientific groups.

The TbAlGe compound was claimed by Yanson (1975) to adopt the DyAlGe type (Cmc2<sub>1</sub> space group) with lattice parameters as  $a=0.4121$ ,  $b=1.052$ ,  $c=0.5831$  from X-ray powder diffraction of alloy which was obtained by arc melting and homogenized at 770 K. At variance with these data, Zhao and Parthé (1990) announced that this phase had the YAlGe type structure with Cmc space group and lattice parameters  $a=0.4044$ ,  $b=1.0434$ ,  $c=0.5767$  (X-ray powder diffraction). The sample was obtained by arc melting the proper amounts of pure components in an argon atmosphere (Tb, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for 100 h in a silica tube.

Zarechnyuk et al. (1970) observed the  $\text{CaAl}_2\text{Si}_2$  type for the  $\text{TbAl}_2\text{Ge}_2$  compound ( $a=0.424$ ,  $c=0.663$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

$\text{Tb}_2\text{Al}_3\text{Ge}_4$  was announced to crystallize with the  $\text{Ba}_2\text{Cd}_3\text{Bi}_4$  type,  $a=0.5914$ ,  $b=1.4834$ ,  $c=0.7720$  (X-ray powder diffraction, Zhao and Parthé 1991b). The sample was obtained by arc melting the proper amounts of pure components in an argon atmosphere (Ce, Al and Ge: 99.99 mass%). The resulting alloy was annealed at 770 K for two months in an Ar-filled silica tube.

### 3.2.11. *Dy–Al–Ge*

Formation and crystal structure of three compounds have been reported in the Dy–Al–Ge system.

DyAlGe was claimed by Yanson (1975) to crystallize with a new structure type (Cmc2<sub>1</sub> space group) with lattice parameters  $a=0.4091$ ,  $b=1.046$ ,  $c=0.5903$  (X-ray powder diffraction data) from the alloy which was synthesized by arc melting and annealed at 770 K. At variance with these data, Zhao and Parthé (1990) announced the YAlGe type for DyAlGe with Cmc space group and lattice parameters  $a=0.4035$ ,  $b=1.0396$ ,  $c=0.5752$

(X-ray powder diffraction). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Dy, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for 100 h in a silica tube.

Zarechnyuk et al. (1970) observed the  $\text{CaAl}_2\text{Si}_2$  type for the  $\text{DyAl}_2\text{Ge}_2$  compound ( $a = 0.421$ ,  $c = 0.667$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

$\text{Dy}_2\text{Al}_3\text{Ge}_4$  was reported to crystallize with the  $\text{Ba}_2\text{Cd}_3\text{Bi}_4$  type,  $a = 0.5881$ ,  $b = 1.4800$ ,  $c = 0.7690$  (X-ray powder diffraction, Zhao and Parthé 1991b). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Dy, Al and Ge: 99.99 mass%). The resulting alloy was annealed at 770 K for two months in an Ar-filled silica tube.

### 3.2.12. Ho–Al–Ge

No phase diagram has been constructed for the ternary Ho–Al–Ge system, however data on the formation and crystal structure of three compounds exist due to the independent investigations of research groups from L'viv University and Geneva University.

The HoAlGe compound was claimed by Yanson (1975) to adopt a DyAlGe type ( $\text{Cmc}2_1$  space group) with lattice parameters  $a = 0.4123$ ,  $b = 1.040$ ,  $c = 0.5827$  (X-ray powder diffraction data). For sample preparation, see Dy–Al–Ge. At variance with these data, Zhao and Parthé (1990) found the YAlGe type structure with  $\text{Cmcm}$  space group and lattice parameters  $a = 0.4031$ ,  $b = 1.0357$ ,  $c = 0.5729$  for this alloy (X-ray powder diffraction). Samples were obtained by arc melting the proper amounts of pure components in an argon atmosphere (Ho, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for 100 h in a silica tube.

Zarechnyuk et al. (1970) observed the  $\text{CaAl}_2\text{Si}_2$  type for the  $\text{HoAl}_2\text{Ge}_2$  compound ( $a = 0.4196$ ,  $c = 0.6668$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

$\text{Ho}_2\text{Al}_3\text{Ge}_4$  was announced to crystallize with the  $\text{Ba}_2\text{Cd}_3\text{Bi}_4$  type,  $a = 0.5865$ ,  $b = 1.4765$ ,  $c = 0.7657$  (X-ray powder diffraction; Zhao and Parthé 1991b). The sample was obtained by arc melting the proper amounts of pure components in an argon atmosphere (Ho, Al and Ge: 99.99 mass%). The resulting alloy was annealed at 770 K for two months in an Ar-filled silica tube.

### 3.2.13. Er–Al–Ge

Formation and crystal structure of three compounds have been reported in the Er–Al–Ge system.

The ErAlGe compound was claimed by Yanson (1975) to adopt a DyAlGe type ( $\text{Cmc}2_1$  space group) with lattice parameters  $a = 0.4101$ ,  $b = 1.034$ ,  $c = 0.5840$  (X-ray powder diffraction data). The alloy was synthesized in the same manner as DyAlGe. At variance with these data, Zhao and Parthé (1990) found that this phase had the YAlGe type

structure with  $Cmcm$  space group and lattice parameters  $a = 0.4010$ ,  $b = 1.0314$ ,  $c = 0.5704$  (X-ray powder diffraction). Samples were obtained by arc melting the proper amounts of the pure components in an argon atmosphere (Er, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for 100 h in a silica tube.

Zarechnyuk et al. (1970) observed the  $CaAl_2Si_2$  type for the  $ErAl_2Ge_2$  compound ( $a = 0.4184$ ,  $c = 0.6662$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

$Er_2Al_3Ge_4$  was announced to crystallize with a  $Ba_2Cd_3Bi_4$  type,  $a = 0.5838$ ,  $b = 1.4747$ ,  $c = 0.7637$  (X-ray powder diffraction; Zhao and Parthé 1991b). Samples were obtained by arc melting the appropriate amounts of the pure components in an argon atmosphere (Er, Al and Ge: 99.99 mass%). The resulting alloy was annealed at 770 K for two months in an Ar-filled silica tube.

#### 3.2.14. *Tm–Al–Ge*

Little information exists on the ternary Tm–Al–Ge system; however two ternary compounds were observed and characterized.

Contrary to the data presented by Yanson (1975) for the TmAlGe compound (DyAlGe type,  $a = 0.402$ ,  $b = 1.033$ ,  $c = 0.5865$ ; X-ray powder diffraction), Zhao and Parthé (1990) indicated the YAlGe type for the compound of equiatomic composition ( $Cmcm$  space group,  $a = 0.4010$ ,  $b = 1.0314$ ,  $c = 0.5704$ ; X-ray powder diffraction). Samples were obtained by arc melting the proper amounts of the pure components in an argon atmosphere (Tm, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for 100 h in a silica tube.

Zarechnyuk et al. (1970) observed the  $CaAl_2Si_2$  type for the  $TmAl_2Ge_2$  compound ( $a = 0.4184$ ,  $c = 0.6662$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks, and finally quenched in water. The purity of the starting components was greater than 99.9 mass%.

#### 3.2.15. *Yb–Al–Ge*

Formation and crystal structure of three compounds have been reported in the Yb–Al–Ge system.

The YbAlGe compound was claimed by Yanson (1975) to adopt a DyAlGe type ( $Cmc2_1$  space group) with lattice parameters  $a = 0.4307$ ,  $b = 1.057$ ,  $c = 0.5935$ . For experimental details, see Dy–Al–Ge.

Zarechnyuk et al. (1970) observed the  $CaAl_2Si_2$  type for the  $YbAl_2Ge_2$  compound ( $a = 0.4118$ ,  $c = 0.705$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

$Yb_7Al_5Ge_8$  was reported by Zhao and Parthé (1991c) to crystallize with a new structure type,  $a = 1.5958$ ,  $b = 0.42871$ ,  $c = 1.2611$ ,  $\beta = 95.78^\circ$  (X-ray single-crystal data). A single crystal was obtained from the as-cast sample which was prepared by reaction of the pure

metals in a high-frequency furnace under an argon atmosphere (Yb 99.9, Al 99.99 and Ge 99.99 mass%). The reaction was observed at a temperature of about 773 K and the sample was left in the furnace at 1000 K for half an hour.

### 3.2.16. Lu–Al–Ge

Little information exists on the ternary Lu–Al–Ge system; however two ternary compounds were observed and characterized.

Zhao and Parthé (1990) indicated the YAlGe type structure for the LuAlGe compound (Cmcm space group,  $a=0.3999$ ,  $b=1.0227$ ,  $c=0.5659$ ; X-ray powder diffraction). Samples were obtained by arc melting the proper amounts of the pure components in an argon atmosphere (Lu, Al and Ge: 99.99 mass%). The alloy was annealed at 870 K for 100 h in a silica tube.

Zarechnyuk et al. (1970) observed the  $\text{CaAl}_2\text{Si}_2$  type for the  $\text{LuAl}_2\text{Ge}_2$  compound ( $a=0.417$ ,  $c=0.663$ ; X-ray powder diffraction). The alloy was prepared by arc melting the elements in purified argon and annealing at 770 K for two weeks. Finally the sample was quenched in water. The purity of the starting components was greater than 99.9 mass%.

## 3.3. R–Ga–Ge systems

### 3.3.1. Y–Ga–Ge

Investigations in the ternary system Y–Ga–Ge are due to Belyavina et al. (1996). Five ternary compounds were found to exist from X-ray powder phase analysis:  $\text{Y}_{1.13}\text{Ga}_{0.5-1.0}\text{Ge}_{3.37-2.87}$  (SmNiGe<sub>3</sub>-type structure,  $a=0.3984$ ,  $b=2.0703$ ,  $c=0.4120$ );  $\text{Y}_2\text{Ga}_{2.70-3.60}\text{Ge}_{4.30-3.40}$  ( $\text{La}_2\text{AlGe}_6$  type,  $a=0.7969$ ,  $b=1.0550$ ,  $c=2.0763$ ,  $\gamma=100.97^\circ$ );  $\text{Y}_{2.25}\text{Ga}_{0.67}\text{Ge}_{6.08}$  ( $\text{Pr}_2\text{LiGe}_6$  type,  $a=0.3956$ ,  $b=2.0763$ ,  $c=0.4100$ );  $\text{Y}_3\text{Ga}_{1.4-3.0}\text{Ge}_{3.6-2.0}$  ( $\alpha\text{-GdSi}_2$  type);  $\text{Y}_3\text{Ga}_{3.4}\text{Ge}_{1.6}$  ( $\alpha\text{-ThSi}_2$  type). Samples were prepared by arc melting high purity components and annealed at 670 K.

### 3.3.2. Ce–Ga–Ge

While no phase diagram is available for the Ce–Ga–Ge system, X-ray phase analysis of 180 ternary alloys indicated the formation of four ternary compounds in the Ce–Ga–Ge system (Gryniv et al. 1989). Alloys were synthesized by arc melting metal ingots in an argon atmosphere followed by annealing at 870 K.

$\text{Ce}_2\text{Ga}_{1.6}\text{Ge}_{5.4}$  was observed to crystallize with a new structure type,  $a=0.8664$ ,  $b=0.8307$ ,  $c=2.1550$  (Gryniv et al. 1989).  $\text{Ce}_4\text{Ga}_4\text{Ge}_7$  belongs to the  $\text{La}_4\text{Ga}_4\text{Ge}_7$  type with lattice parameters  $a=0.8414$ ,  $b=0.8620$ ,  $c=3.109$  (Gryniv et al. 1989). CeGaGe is reported to form the  $\alpha\text{-ThSi}_2$  type,  $a=0.4292$ ,  $c=1.4518$ .  $\text{Ce}_5\text{Ga}_2\text{Ge}$  was found to adopt the  $\text{Cr}_5\text{B}_3$  structure type,  $a=0.8019$ ,  $c=1.3850$  (Gryniv et al. 1989).

### 3.3.3. Nd–Ga–Ge

Five ternary compounds were observed and characterized for the Nd–Ga–Ge system from X-ray powder diffraction of alloys which were arc melted and annealed at 870 K (Opainych et al. 1992). Crystallographic data for these compounds are as follows:

$\text{Nd}_2(\text{Ga}_x\text{Ge}_{1-x})_7$ ,  $\text{Ce}_2(\text{Ga},\text{Ge})_7$  type,  $a=0.8511\text{--}0.8552$ ,  $b=0.8151\text{--}0.863$ ,  $c=2.1210\text{--}2.1379$ ;  $\text{Nd}_4(\text{Ga}_x\text{Ge}_{1-x})_{11}$ ,  $x=0.33\text{--}0.43$ ,  $\text{La}_4(\text{Ga},\text{Ge})_{11}$  type,  $a=0.8213\text{--}0.8314$ ,  $b=0.8311\text{--}0.8463$ ,  $c=0.3591\text{--}0.3600$ ;  $\text{NdGa}_{1+x}\text{Ge}_{1-x}$ ,  $x=0\text{--}0.2$ ,  $\alpha\text{-ThSi}_2$  type,  $a=0.4240\text{--}0.4238$ ,  $c=1.4511\text{--}1.4510$ ;  $\text{Nd}(\text{Ga}_x\text{Ge}_{1-x})_2$ ,  $x=0.75\text{--}0.85$ ,  $\text{AlB}_2$  type,  $a=0.4247\text{--}0.4231$ ,  $c=0.4245\text{--}0.4229$ ;  $\text{Nd}_5(\text{Ga}_{0.53}\text{Ge}_{0.47})_3$ ,  $\text{Cr}_5\text{B}_3$  type,  $a=0.7939$ ,  $c=1.3908$ .

### 3.3.4. Gd–Ga–Ge

Golovata et al. (1996) reported results of the X-ray powder phase analysis of alloys of Gd–Ga–Ge system at 1070 K and 670 K. Six ternary compounds were found to exist. They are  $\text{GdGa}_{0.32\text{--}0.55}\text{Ge}_{3.00\text{--}2.77}$ ,  $\text{Gd}_2\text{Ga}_{2.34\text{--}3.58}\text{Ge}_{4.66\text{--}3.42}$ ,  $\text{GdGa}_{3.00\text{--}3.09}\text{Ge}_{0.50\text{--}0.41}$ ,  $\text{GdGa}_{0.29\text{--}0.36}\text{Ge}_{1.93\text{--}1.86}$ ,  $\text{GdGa}_{1.21\text{--}1.36}\text{Ge}_{0.82\text{--}0.67}$ , and  $\text{GdGa}_{0.03\text{--}0.13}\text{Ge}_{0.88\text{--}0.78}$ . The crystal structure and lattice parameters were determined for two compounds by X-ray powder diffraction:  $\text{GdGa}_{0.32\text{--}0.55}\text{Ge}_{3.00\text{--}2.77}$  (SmNiGe<sub>3</sub> type,  $a=0.4005$ ,  $b=2.0826$ ,  $c=0.4161$  for  $\text{GdGa}_{0.32}\text{Ge}_{3.00}$ ) and  $\text{Gd}_2\text{Ga}_{2.34\text{--}3.58}\text{Ge}_{4.66\text{--}3.42}$  ( $\text{La}_2\text{AlGe}_6$  type,  $a=0.8182$ ,  $b=1.0812$ ,  $c=0.8420$ ,  $\gamma=100.85^\circ$  for  $\text{GdGa}_{3.15}\text{Ge}_{3.85}$ ).

### 3.3.5. Tm–Ga–Ge

The formation of eight ternary compounds is reported for the Tm–Ga–Ge system (Gryniv and Myakush 1989) from arc-melted samples annealed at 870 K. They are:  $\text{Tm}_2\text{Ga}_{0.5}\text{Ge}_{4.5}$  (new structure type,  $a=0.3915$ ,  $b=0.4048$ ,  $c=1.8209$ ; X-ray powder diffraction),  $\text{TmGa}_{1.94}\text{Ge}_{0.06}$  ( $\text{AlB}_2$  type,  $a=0.4171$ ,  $c=0.3995$ ; X-ray powder diffraction),  $\text{Tm}_3(\text{Ga}_{0.5}\text{Ge}_{0.5})_5$  (new structure type,  $a=0.7748$ ,  $c=1.0836$ ; X-ray single-crystal method),  $\text{Tm}_{10}\text{Ga}_6\text{Ge}_9$  (unknown structure type),  $\text{Tm}_{11}\text{Ga}_2\text{Ge}_{12}$  (unknown type),  $\text{Tm}_3\text{Ga}_{3.2\text{--}2.4}\text{Ge}_{0.4\text{--}1.2}$  (unknown type),  $\text{Tm}_5\text{Ga}_3\text{Ge}_2$  (unknown type),  $\text{Tm}_4\text{Ga}_7\text{Ge}_9$  (unknown type).

## 3.4. R–In–Ge systems

No phase diagrams exist for the R–In–Ge system, however a series of ternary compounds,  $\text{La}_2\text{InGe}_2$ , have been observed and characterized by Zaremba et al. (1997) (see table 4).

Table 4  
Lattice parameters for the  $\text{R}_2\text{InGe}_2$  compounds,  $\text{Mo}_2\text{FeB}_2$ -type<sup>a</sup>

Compound	Lattice parameters (nm)		Compound	Lattice parameters (nm)	
	<i>a</i>	<i>c</i>		<i>a</i>	<i>c</i>
$\text{Y}_2\text{InGe}_2$	0.7339	0.4242	$\text{Gd}_2\text{InGe}_2$	0.7378	0.4248
$\text{La}_2\text{InGe}_2$	0.7664	0.4450	$\text{Tb}_2\text{InGe}_2$	0.7337	0.4215
$\text{Ce}_2\text{InGe}_2$	0.7577	0.4391	$\text{Dy}_2\text{InGe}_2$	0.7322	0.4187

<sup>a</sup> Source: Zaremba et al. (1997).

Alloys were synthesized by arc melting pure metals (99.9 mass% R; 99.99 mass% In and Ge) followed by annealing for 700 h at 870 K in evacuated quartz tubes. Crystal structure was investigated by the single-crystal method for the  $\text{La}_2\text{InGe}_2$  compound, for other phases the X-ray powder method was employed.

### 3.5. R–C–Ge systems

The only information on the interaction of the components in the ternary R–C–Ge systems is due to Mayer and Shidlowky (1969), who investigated the crystal structure of  $\text{R}_5\text{CGe}_3$  compounds. They were found to form a partly filled  $\text{Mn}_5\text{Si}_3$  type. Crystallographic characteristics of the isotypic  $\text{R}_5\text{CGe}_3$  series are listed in table 5. The samples were synthesized by melting of the pure components in an induction furnace at 1773–1873 K.

Table 5  
Lattice parameters for the  $\text{R}_5\text{CGe}_3$  compounds,  $\text{Mn}_5\text{Si}_3$ -type<sup>a</sup>

### 3.6. R–Si–Ge systems

#### 3.6.1. Y–Si–Ge

The isothermal section of the Y–Si–Ge phase diagram at 870 K was constructed by Muratova (1976) using X-ray powder diffraction data of arc-melted alloys annealed for 400 h. The purity of the starting components was greater than 99.90 mass%. The phase relations are characterized by the existence of two ternary compounds and by the formation of three continuous solid solutions between isostructural binary compounds:  $\text{Y}_5(\text{Si,Ge})_3$ ,  $\text{Y}(\text{Si,Ge})$  and  $\text{Y}_2(\text{Si,Ge})_3$  (fig. 18). Three extended ranges of solid solutions were found to exist within the Y–Si–Ge system at 870 K, originating at  $\text{Y}_5\text{Ge}_4$ ,  $\text{Y}_{11}\text{Ge}_{10}$  and  $\text{YGe}_2$ , which dissolve 20, 15 and 37 at.% Si, respectively.

$\text{YSi}_{1.4}\text{Ge}_{0.6}$  (1) was reported to crystallize with the  $\alpha\text{-GdSi}_2$  type,  $a=0.4044$ ,  $b=0.3988$ ,  $c=1.348$  (Muratova 1976; X-ray powder diffraction). For the experimental procedure, see above.

$\text{YSi}_{1.8}\text{Ge}_{0.2}$  (2) belongs to the  $\alpha\text{-ThSi}_2$  type,  $a=0.4002$ ,  $c=1.336$  (Muratova 1976; X-ray powder diffraction). The samples were synthesized in the same manner as that applied for the investigation of the Y–Si–Ge isothermal section.

Fig. 18. Y-Si-Ge, isothermal section at 870 K.

3.6.2. La-Si-Ge

The phase equilibria in the La-Si-Ge system at 870 K (fig. 19) were investigated by Muratova et al. (1974) and Bodak and Muratova (1981) by means of X-ray phase analysis of alloys which were arc melted and subsequently annealed in evacuated silica tubes for 400 h and finally quenched in water. Starting materials were La 99.79 mass%,

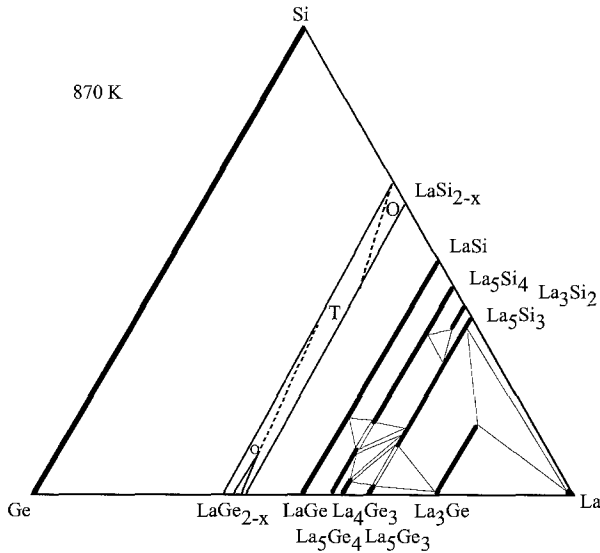

Fig. 19. La-Si-Ge, isothermal section at 870 K.

Si 99.9 mass% and Ge 99.99 mass%. Phase relations are characterized by the formation of continuous solid solution originating at the isotypic binary compounds LaSi and LaGe. A complete solid solution with successive changing of the tetragonal  $\alpha$ -ThSi<sub>2</sub> (T) and orthorhombic  $\alpha$ -GdSi<sub>2</sub> (O) structure types was also observed between LaSi<sub>2-x</sub> and LaGe<sub>2-x</sub>. No ternary compounds were found. La<sub>3</sub>Ge and La<sub>5</sub>Ge<sub>4</sub> dissolve 15 and 10 at.% Si. Solubilities of Ge in La<sub>5</sub>Si<sub>3</sub> and La<sub>5</sub>Si<sub>4</sub> were reported to be approximately 27.5 and 29.5 at.%, respectively.

### 3.6.3. Ce-Si-Ge

Investigations in the ternary system Ce-Si-Ge were performed by two different research groups, i.e. Haschke et al. (1966) and Bodak and Muratova (1979).

Phase relations in an isothermal section at 1070 K were determined by Haschke et al. (1966) by means of X-ray powder diffraction methods (fig. 20). Samples were synthesized by heating compacted mixtures of 99.9 mass% purity for a few minutes in an induction furnace slightly above the melting point. The formation of two complete solid solutions was reported: Ce(Si,Ge) and Ce(Si,Ge)<sub>2-x</sub>. No ternary compounds were observed.

A partial isothermal section at 870 K within 0–50 at.% Ce is presented in fig. 21 from X-ray powder analysis of 92 alloys which were arc melted from ingots of pure metals and annealed in evacuated quartz tubes for 400 h (Bodak and Muratova 1979). The purity of the metals was greater than 99.9 mass%. A continuous solid solution with successive changing of the  $\alpha$ -ThSi<sub>2</sub> (T) and  $\alpha$ -GdSi<sub>2</sub> (O) structure types was observed between CeSi<sub>2-x</sub> and CeGe<sub>2-x</sub>. No ternary compounds were found.

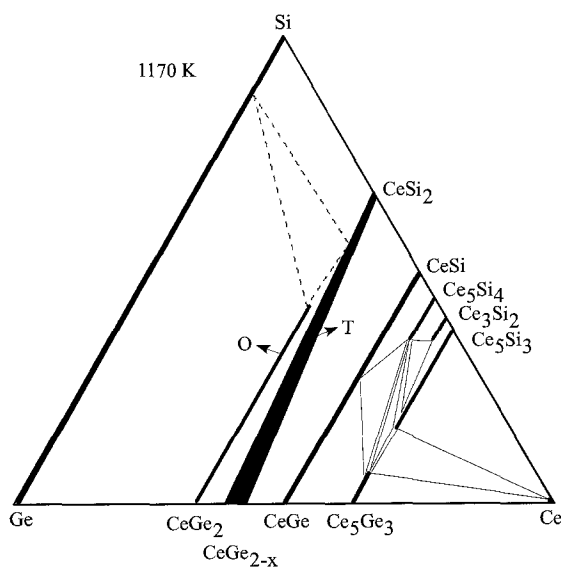

Fig. 20. Ce-Si-Ge, isothermal section at 1170 K.

Fig. 21. Ce–Si–Ge, partial isothermal section at 870 K (0–40 at.% Ce).

### 3.6.4. Pr–Si–Ge

The phase relations in the Pr–Si–Ge ternary system at 873 K were investigated by Muratova and Bodak (1974) using X-ray powder analysis (fig. 22). Samples were obtained by arc melting, and homogenized at 873 K for 500 h. No ternary compounds were found, but a continuous solid solution  $\text{Pr}(\text{Si},\text{Ge})_{2-x}$  was observed. The solubilities of germanium

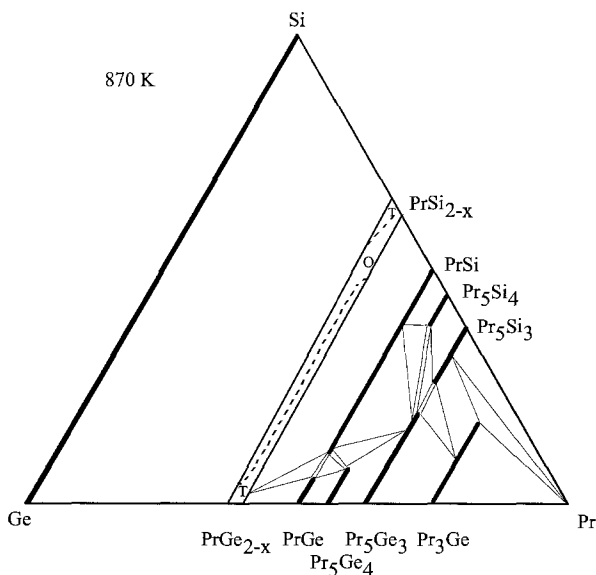

Fig. 22. Pr–Si–Ge, isothermal section at 870 K.

in  $\text{Pr}_5\text{Si}_3$ ,  $\text{Pr}_5\text{Si}_4$  and  $\text{PrSi}$  were determined as 12.5, 7 and 40 at.%, respectively, whereas  $\text{Pr}_3\text{Ge}$  and  $\text{Pr}_5\text{Ge}_3$  dissolve 18 and 20 at.% Si, respectively.

Muratova (1974) reported on the X-ray powder investigation of the crystal structure of alloys within the homogeneity field  $\text{Pr}(\text{Si},\text{Ge})_{2-x}$ . The Ge-rich region of solid solution was found to crystallize with a tetragonal  $\alpha\text{-ThSi}_2$  type (T). With increasing Ge/Si exchange, a continuous transition into the orthorhombic  $\alpha\text{-GdSi}_2$  (O) was observed; no two-phase field was established.

### 3.6.5. Gd–Si–Ge

The phase equilibria in the Gd–Si–Ge system at 870 K (fig. 23) were investigated by Muratova et al. (1975) by means of X-ray phase analysis of alloys which were arc melted and subsequently annealed in evacuated silica tubes for 400 h and finally quenched in water. The purity of the starting materials was greater than 99.9 mass%. No ternary compounds were observed. Phase relations are characterized by the existence of three continuous solid solutions:  $\text{Gd}(\text{Si},\text{Ge})_{2-x}$ ,  $\text{Gd}_5(\text{Si},\text{Ge})_3$  and  $\text{Gd}_2(\text{Si},\text{Ge})_3$ . The crystal structure of  $\text{Gd}(\text{Si},\text{Ge})_{2-x}$  solid solution was said to change with increasing Si content from  $\alpha\text{-GdSi}_2$  (O) type through  $\alpha\text{-ThSi}_2$  type (T) to  $\alpha\text{-GdSi}_2$  (O) type (Muratova 1974; X-ray powder diffraction). Binary compounds  $\text{GdGe}$ ,  $\text{GdSi}$  and  $\text{Gd}_5\text{Ge}_4$  dissolve 33, 10 and 8 at.% of third component respectively (Muratova et al. 1975).

During a study of the magnetic properties of alloys heat treated at 1870 K for 5 hours in the pseudobinary system  $\text{Gd}_5(\text{Si}_x\text{Ge}_{1-x})_4$ , Holtzberg et al. (1967) report extended solubility of Si in  $\text{Gd}_5\text{Ge}_4$  ( $0.0 \leq x \leq 0.3$ ) and Ge in  $\text{Gd}_5\text{Si}_4$  ( $0.5 \leq x \leq 1.0$ ). They also

Fig. 23. Gd–Si–Ge, isothermal section at 870 K.

acknowledge the existence of the ternary intermediate phase with unidentified crystal structure extending between  $0.3 < x < 0.5$ . These seemingly contradicting experimental results regarding the phase relations in the  $\text{Gd}_5\text{Ge}_4$ – $\text{Gd}_5\text{Si}_4$  pseudobinary system suggest that the  $\text{Gd}_5\text{Si}_4$ -based solid solution and the ternary phase are probably high-temperature phases, which decompose during the heat treatment between 870 K and 1870 K, and that the solid solubility of Si in  $\text{Gd}_5\text{Ge}_4$  is strongly temperature dependent.

Pecharsky and Gschneidner (1997) investigated 12 as-cast alloys from the pseudobinary system  $\text{Gd}_5(\text{Si}_x\text{Ge}_{1-x})_4$  by X-ray single-crystal and powder diffraction. The  $\text{Gd}_5\text{Si}_4$ -based solid solution where Ge statistically substitutes for Si maintains the  $\text{Sm}_5\text{Ge}_4$ -type orthorhombic crystal structure of the binary  $\text{Gd}_5\text{Si}_4$  compound and extends from  $0.5 < x \leq 1$ . The  $\text{Gd}_5\text{Ge}_4$ -based solid solution where Si statistically substitutes for Ge also maintains the  $\text{Sm}_5\text{Ge}_4$ -type orthorhombic crystal structure of the binary  $\text{Gd}_5\text{Si}_4$  compound and extends from  $0 < x \leq 0.2$ . The crystal structure of the ternary phase, which exists for  $0.24 \leq x \leq 0.5$ , has been determined for the first time, and it was shown to be a monoclinically distorted derivative of orthorhombic  $\text{Sm}_5\text{Ge}_4$ -type (P112<sub>1</sub>/a space group,  $a=0.75808$ ,  $b=1.4802$ ,  $c=0.77799$ ,  $\gamma=93.190$ ) for  $\text{Gd}_5\text{Si}_2\text{Ge}_2$ .

## 4. R–d element–germanium systems

### 4.1. Sc–d element–Ge systems

#### 4.1.1. Sc–V–Ge

The phase equilibria in the Sc–V–Ge system were investigated by Kotur (1987) by means of X-ray analysis of alloys which were arc melted and subsequently annealed in evacuated silica tubes for 350–650 h at 1070 K and finally quenched in water (fig. 24). Starting

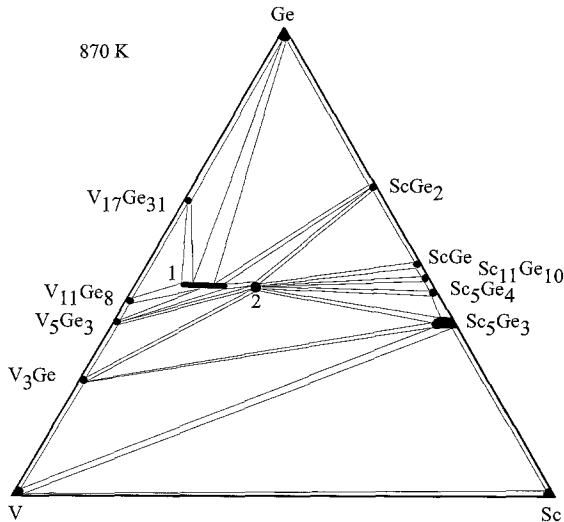

Fig. 24. Sc–V–Ge, isothermal section at 870 K.

materials were Sc 99.92 mass%, V 99.9 mass% and Ge 99.99 mass%.

Two ternary compounds were observed at 1070 K:  $\text{Sc}_{1-1.8}\text{V}_{5-4.2}\text{Ge}_5$  (1) with the  $\text{V}_6\text{Si}_5$ -type structure ( $a=0.7872$ – $0.7850$ ,  $c=0.5091$ – $0.5157$ ) and  $\text{Sc}_2\text{V}_3\text{Ge}_4$  (2) with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$ -type structure ( $a=0.6614$ ,  $b=1.2774$ ,  $c=0.6776$ ) (Kotur et al. 1986).

Kotur et al. (1983) reported on the preliminary X-ray single-crystal investigation of a  $\text{Sc}_x\text{V}_{5-x}\text{Ge}_3$  sample which was isotypic to  $\text{Sc}_5\text{Ge}_3$  ( $a=0.743$ ,  $c=0.502$ ). The single crystal was obtained from a cast alloy. This phase is not shown in the 870 K isothermal section, fig. 24.

#### 4.1.2. Sc–Cr–Ge

The isothermal section of the Sc–Cr–Ge phase diagram at 1070 K was constructed by Kotur et al. (1988b). The phase relations are characterized by the formation of four ternary compounds and by the existence of a solid solution range of Cr in  $\text{Sc}_5\text{Ge}_3$  (7.5 at.%) (fig. 25). For details of sample preparation, see Sc–V–Ge.

Venturini et al. (1985a) investigated the crystal structure of the  $\text{ScCrGe}_2$  (3) compound (TiMnSi<sub>2</sub>-type structure:  $a=0.937$ ,  $b=1.009$ ,  $c=0.813$ ). The sample was arc melted and annealed at 1073 K in an evacuated quartz capsule. The purity of the starting materials was 99.9 mass%.

Kotur et al. (1988a) confirmed the existence of this compound with similar lattice parameters ( $a=0.9355$ ,  $b=1.0148$ ,  $c=0.8141$ ) and investigated the crystal structure of the other three compounds:  $\text{ScCr}_6\text{Ge}_6$  (1) with the  $\text{HfFe}_6\text{Ge}_6$ -type ( $a=0.5102$ ,  $c=0.8229$ ),  $\text{Sc}_2\text{Cr}_4\text{Ge}_5$  (2) with the  $\text{Nb}_2\text{Cr}_4\text{Si}_5$ -type ( $a=0.7821$ ,  $b=1.6662$ ,  $c=0.5146$ ) and  $\text{Sc}_7\text{Cr}_{4+x}\text{Ge}_{10-x}$  ( $x=1.3$ ) (4) with the  $\text{Sc}_7\text{Cr}_{4+x}\text{Si}_{10-x}$  type ( $a=1.0150$ ,  $c=1.4352$ ).

Fig. 25. Sc–Cr–Ge, isothermal section at 1070 K.

Fig. 26. Sc–Mn–Ge, isothermal section at 870 K.

#### 4.1.3. Sc–Mn–Ge

The ternary phase diagram of the Sc–Mn–Ge system at 870 K was studied by means of X-ray powder diffraction by Andrusyak and Kotur (1991) (fig. 26). For sample preparation, see Sc–V–Ge. Six ternary manganese germanides of scandium were found and investigated (Andrusyak 1988).

Crystallographic data for the ternary compounds which were observed in the course of phase-equilibrium studies in the Sc–Mn–Ge system at 870 K are listed in table 6.

Venturini et al. (1992) investigated the crystal structure for the  $\text{ScMn}_6\text{Ge}_6$  compound at 1073 K and confirmed the same structure type with similar lattice parameters. The alloy was synthesized by a powder metallurgical reaction in an evacuated silica tube at 1073 K for 14 days.

Fig. 27. Sc-Fe-Ge, isothermal section at 870 K.

#### 4.1.4. Sc-Fe-Ge

The phase-field distribution in the Sc-Fe-Ge system at 870 K is characterized by the formation of eight ternary compounds and by the existence of substitutional exchange of Ge/Fe in the solid solutions  $\text{Sc}_5(\text{Fe}_x\text{Ge}_{1-x})_3$  for  $0 < x < 0.15$  and  $\text{Sc}(\text{Fe}_x\text{Ge}_{1-x})_2$  for  $0 < x < 0.1$  after Andrusyak and Kotur (1991) (fig. 27). For details of sample preparation, see Sc-V-Ge. The starting materials were Sc 99.92 mass%, Fe 99.95 mass%, and Ge 99.99 mass%.

<sup>a</sup> For ScFe<sub>1.79</sub>Ge<sub>0.21</sub>.

The  $\text{ScFe}_6\text{Ge}_6$  compound with the  $\text{HfFe}_6\text{Ge}_6$ -type was observed by Olenych et al. (1981). Samples were obtained by arc melting and annealing for 300 h at 1070 K. Andrusyak (1986) and Venturini et al. (1992) confirmed the formation and crystal structure of this compound at 870 K and 1173 K respectively.

The existence and structural characteristics of the  $\text{ScFeGe}_2$  compound at 1073 K was reported by Venturini et al. (1985a) (X-ray powder diffraction method) and was confirmed by Andrusyak and Kotur (1991) at 870 K.

The formation and crystal structure of six other ternary compounds were reported by Kotur and Andrusyak (1984a), Andrusyak and Kotur (1989, 1991).

Crystallographic data on the ternary Sc–Fe–Ge compounds are listed in table 7.

#### 4.1.5. Sc–Co–Ge

A systematic study of the Sc–Co–Ge system at 870 K was performed by Kotur and Andrusyak (1991). For sample preparation, see Sc–V–Ge. The starting materials were Sc 99.92 mass%, Co 99.92 mass% and Ge 99.99 mass%. Seven ternary compounds were found to exist (see fig. 28). The limits of solid solutions originating at  $\text{ScCo}_2$ ,  $\text{ScGe}_2$ ,  $\text{Sc}_{11}\text{Ge}_{10}$ ,  $\text{Sc}_5\text{Ge}_4$  and  $\text{Sc}_5\text{Ge}_3$  were established as 11.5 at.% Ge and 6 at.%, 4 at.%, 4 at.%, 3 at.% Co, respectively, by means of X-ray powder diffraction. The lattice parameter of  $\text{ScCo}_{2-1.65}\text{Ge}_{0-0.35}$  varies linearly within  $a = 0.6902-0.6984$ . Similarly for  $\text{ScGe}_2$  the solid-solution range of Co is given by  $\text{ScCo}_{0-0.18}\text{Ge}_{2-1.82}$  (Kotur 1995).

The crystallographic characteristics for the ternary Sc–Co–Ge compounds are presented in table 8.

A single crystal of the  $\text{Sc}_3\text{Co}_2\text{Ge}_3$  compound, which is not shown in fig. 28, was obtained from an arc-melted and slowly cooled sample:  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  type,  $a = 0.4078$ ,  $b = 0.9930$ ,  $c = 1.3243$  (Kotur and Andrusyak 1991).

#### 4.1.6. Sc–Ni–Ge

In the course of phase-equilibrium studies in the Sc–Ni–Ge system at 870 K, Kotur and Andrusyak (1991) observed eight ternary nickel germanides of scandium (see fig. 29). For details of sample preparation, see Sc–V–Ge. The binary germanides of scandium dissolve 2–8 at.% Ni; the solubility of Ge in ScNi<sub>2</sub> is 3.5 at.% (Kotur 1995).

Crystallographic data for the ternary Sc–Ni–Ge compounds observed at 870 K are listed in table 9.

Andrusyak (1988) studied the crystal structure of the Sc<sub>9</sub>Ni<sub>5</sub>Ge<sub>8</sub> compound by the

Fig. 29. Sc–Ni–Ge, isothermal section at 870 K.

5 Sc <sub>6</sub> Ni <sub>16</sub> Ge <sub>7</sub>	Mg <sub>6</sub> Cu <sub>16</sub> Si <sub>7</sub>	1.1654			Gladyshevsky et al. (1962)
6 Sc <sub>3</sub> Ni <sub>4</sub> Ge <sub>4</sub>	Gd <sub>6</sub> Cu <sub>8</sub> Ge <sub>8</sub>	1.2910	0.6598	0.3908	Kotur and Sikirica (1982)
7 ScNiGe	TiNiSi	0.6454	0.4071	0.7068	Kotur and Andrusyak (1984a)
8 Sc <sub>13</sub> Ni <sub>6</sub> Ge <sub>15</sub>	unknown				Kotur (1995)

X-ray single-crystal method (own type of structure,  $a=2.0426$ ,  $b=0.9129$ ,  $c=0.39822$ ). The single crystal was obtained from an as-cast sample.

Andrusyak and Kotur (1989) reported on X-ray single-crystal investigation of the Sc<sub>4</sub>Ni<sub>4</sub>Ge<sub>7-x</sub> ( $x=0.8$ ) compound which existed in arc melted alloys and decomposed at 870 K (Zr<sub>4</sub>Co<sub>4</sub>Ge<sub>7</sub> type,  $a=1.3276$ ,  $c=0.5225$ ).

Neither of these two phases are shown in the 870 K isothermal section, fig. 29.

#### 4.1.7. Sc–Cu–Ge

Kotur and Andrusyak (1984b) studied phase equilibria in the Sc–Cu–Ge system (fig. 30)

Fig. 30. Sc–Cu–Ge, isothermal section at 870 K.

and reported the existence of two compounds at 870 K. For sample preparation, see Sc–V–Ge.

The crystal structure for the  $\text{Sc}_3\text{Cu}_4\text{Ge}_4$  compound (1) was studied by Thirion et al. (1983) ( $\text{Gd}_6\text{Cu}_8\text{Ge}_8$  type,  $a=1.330$ ,  $b=0.6516$ ,  $c=0.3996$ ) and was confirmed by Kotur and Andrusyak (1984b) ( $a=1.332$ ,  $b=0.6523$ ,  $c=0.4004$ ).

The crystallographic characteristics for the ScCuGe compound (2) (ZrNiAl type,  $a=0.6515$ ,  $c=0.3972$ ) reported by Kotur and Andrusyak (1984b) are in good agreement with those announced earlier by Dwight et al. (1973).

#### 4.1.8. Sc–Nb–Ge

The isothermal section of the Sc–Nb–Ge phase diagram at 1070 K was investigated by Kotur (1986) (fig. 31). The phase relations are characterized by the formation of one

Fig. 31. Sc–Nb–Ge, isothermal section at 870 K.

ternary  $\text{Sc}_2\text{Nb}_3\text{Ge}_4$  compound and by the existence of a rather extended substitutional exchange of Sc/Nb in the  $(\text{Sc}_{1-x}\text{Nb}_x)_5\text{Ge}_3$  solid solution for  $0 < x < 0.8$  with the following unit cell dimensions for the Nb-rich end boundary sample:  $a=0.7752$ ,  $c=0.5362$ . For sample preparation, see Sc–V–Ge. The starting components were Sc 99.92 mass%, Nb 99.9 mass%, Ge 99.99 mass%.

$\text{Sc}_2\text{Nb}_3\text{Ge}_4$  belongs to the  $\text{Ce}_2\text{Sc}_3\text{Ge}_4$ -type with lattice parameters  $a=0.6860$ ,  $b=1.339$ ,  $c=0.7160$  (Kotur 1986, X-ray powder diffraction).

#### 4.1.9. Sc–Mo–Ge

The phase diagram for Sc–Mo–Ge was reported by Kotur and Bodak (1988) (fig. 32). For the details of synthesis, see Sc–V–Ge.

Fig. 32. Sc–Mo–Ge, isothermal section at 1070 K.

Only one ternary compound was found to exist at 1070 K,  $\text{Sc}_{2-4}\text{Mo}_{3-1}\text{Ge}_4$  with  $\text{Sm}_5\text{Ge}_4$  structure type,  $a=0.6691\text{--}0.6813$ ,  $b=1.2872\text{--}1.3285$ ,  $c=0.6905\text{--}0.7027$  (X-ray powder diffraction method).

#### 4.1.10. Sc–Ru–Ge

No ternary phase diagram has been established for the Sc–Ru–Ge system, but three ternary compounds have been characterized by various authors.

$\text{ScRuGe}$  crystallizes with the ZrNiAl-type of structure,  $a=0.6962$ ,  $c=0.3468$  (Hovestreydt et al. 1982; X-ray powder diffraction). The sample was arc melted under an argon atmosphere and annealed at 1270 K for 1–2 weeks in an evacuated silica tube.

According to X-ray powder diffraction data reported by Venturini et al. (1985a), the compound  $\text{ScRuGe}_2$  is isostructural with  $\text{TiMnSi}_2$  ( $a=0.928$ ,  $b=1.032$ ,  $c=0.812$ ). For sample preparation, see Sc–Cr–Ge.

Engel et al. (1984) reported the crystal structure of the  $\text{Sc}_4\text{Ru}_7\text{Ge}_6$  compound crystallizing with the  $\text{U}_4\text{Re}_7\text{Si}_6$ -type of structure ( $a=0.8129$ , X-ray powder diffraction data). The sample was prepared by arc melting a cold-pressed mixture of proper amounts of binary  $\text{ScGe}_2$  alloy and ruthenium. The ternary alloy was finally annealed at 1270 K for 5 weeks. The starting materials were Sc 99.95 mass%, Ge 99.999 mass%, Ru 99.9 mass%.

#### 4.1.11. Sc–Rh–Ge

No ternary phase diagram is available for the Sc–Rh–Ge system. However, four ternary phases have been identified.

Hovestreydt et al. (1982) reported two types of structures for the ScRhGe compound: TiNiSi type,  $a=0.6497$ ,  $b=0.4112$ ,  $c=0.7385$  and ZrNiAl type,  $a=0.6672$ ,  $c=0.3794$ . For sample preparation, see Sc–Ru–Ge.

Sc<sub>4</sub>Rh<sub>7</sub>Ge<sub>6</sub> was found to be isostructural with the U<sub>4</sub>Re<sub>7</sub>Si<sub>6</sub>-type ( $a=0.81255$ ) by Engel et al. (1984). The crystal structure was determined on a single crystal and was refined to an  $R$  value of 0.056 for 99 independent reflections. For details concerning the sample preparation, see Sc–Ru–Ge.

ScRhGe<sub>2</sub> was observed to adopt the TiMnSi<sub>2</sub>-type structure ( $a=0.9302$ ,  $b=1.0359$ ,  $c=0.8146$ ) by Parthé and Chabot (1984).

Venturini et al. (1986a) investigated the crystal structure of the Sc<sub>4</sub>Rh<sub>6</sub>Ge<sub>19</sub> compound. It was found to crystallize with its own structure type,  $a=1.2605$ . Samples were obtained by heating a mixture of starting components (Sc, Rh, Ge: 99.999 mass%) in an evacuated quartz tube at 1173 K.

#### 4.1.12. Sc–Pd–Ge

Only one compound was reported for the Sc–Pd–Ge system: ScPdGe, ZrNiAl-type of structure,  $a=0.6715$ ,  $c=0.3925$  (Hovestreydt et al. 1982, X-ray powder diffraction). For sample preparation, see Sc–Ru–Ge.

#### 4.1.13. Sc–Ag–Ge

The isothermal section at 870 K was constructed by Kotur and Boichuk (1988) (fig. 33). For experimental details, see Sc–V–Ge. The starting materials were Sc 99.92 mass%, Ag 99.99 mass%, Ge 99.999 mass%.

Only one compound was found for the Sc–Ag–Ge combination by Kotur and Boichuk (1988): ScAgGe with the ZrNiAl type,  $a=0.6882$ ,  $c=0.4026$ .

Fig. 33. Sc–Ag–Ge, isothermal section at 870 K.

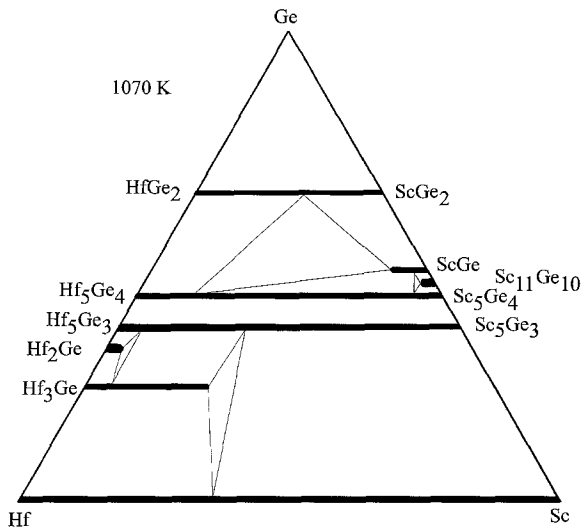

Fig. 34. Sc-Hf-Ge, isothermal section at 1070 K.

#### 4.1.14. Sc-Hf-Ge

The isothermal section of the Sc-Hf-Ge phase diagram at 1070 K was reported by Kotur (1991) (fig. 34). No ternary compounds were observed. Continuous solid solutions between isotopic pairs of binary germanides  $\text{ScGe}_2$ - $\text{HfGe}_2$ ,  $\text{Sc}_5\text{Ge}_4$ - $\text{Hf}_5\text{Ge}_4$  and  $\text{Sc}_5\text{Ge}_3$ - $\text{Hf}_5\text{Ge}_3$  were observed. Also ~25 at.% Sc substitutes for Hf in  $\text{Hf}_3\text{Ge}$ .

#### 4.1.15. Sc-Ta-Ge

The phase-field distribution in the Sc-Ta-Ge system at 1070 K (fig. 35) is characterized

Fig. 35. Sc-Ta-Ge, isothermal section at 1070 K.

by the formation of a ternary  $\text{Sc}_{2-3}\text{Ta}_{3-2}\text{Ge}_4$  compound with a large homogeneity region and by the existence of the  $\text{Sc}_{5-3.25}\text{Ta}_{0-1.75}\text{Ge}_3$  solid solution originating at  $\text{Sc}_5\text{Ge}_3$ , after Kotur and Bodak (1990). For sample preparation, see Sc–V–Ge. Starting materials were Sc 99.92 mass%, Ta 99.99 mass%, Ge 99.99 mass%.

$\text{Sc}_{2-3}\text{Ta}_{3-2}\text{Ge}_4$  was found to crystallize with a  $\text{Sm}_5\text{Ge}_4$  type,  $a=0.6823\text{--}0.6855$ ,  $b=1.3177\text{--}1.3230$ ,  $c=0.6977\text{--}0.6993$ , from X-ray powder diffraction of an arc melted alloy annealed at 1070 K (Kotur and Bodak 1990).

#### 4.1.16. Sc–W–Ge

No ternary compounds were observed by Kotur et al. (1989) in the ternary Sc–W–Ge system at 1070 K (fig. 36). The binary  $\text{Sc}_5\text{Ge}_3$  compound dissolves 3 at.% W. For sample preparation, see Sc–V–Ge.

Fig. 36. Sc–W–Ge, isothermal section at 1070 K.

#### 4.1.17. Sc–Re–Ge

Figure 37 represents the isothermal section of the Sc–Re–Ge system at 1070 K after Kotur (1995). For sample preparation, see Sc–V–Ge. The mutual solid solubility of components in binary compounds is negligible.

In the course of phase studying the equilibria in the Sc–Re–Ge system at 1070 K, the formation of the  $\text{ScReGe}_2$  compound (1) with  $\text{TiMnSi}_2$ -type structure has been confirmed and the existence of two compounds [ $\text{Sc}_3\text{Re}_2\text{Ge}_3$  (2) and  $\text{Sc}_9\text{Re}_3\text{Ge}_8$  (3)] with unknown structures has been observed by Kotur 1995.

The lattice parameters for  $\text{ScReGe}_2$  are as follows  $a=0.939$ ,  $b=1.017$ ,  $c=0.832$  after Venturini et al. (1985a) (powder diffraction data; for sample preparation, see Sc–Cr–Ge) and  $a=0.9385$ ,  $b=1.0173$ ,  $c=0.8323$  after Kotur (1995).

Fig. 37. Sc-Re-Ge, isothermal section at 1070 K.

#### 4.1.18. Sc-Os-Ge

No phase diagram is established for the Sc-Os-Ge system.

ScOsGe was observed to adopt the ZrNiAl-type structure with lattice parameters  $a = 0.6928$ ,  $c = 0.3407$  (Hovestreydt et al. 1982; X-ray powder diffraction analysis). For sample preparation, see Sc-Ru-Ge.

ScOsGe<sub>2</sub> crystallizes with the TiMnSi<sub>2</sub>-type structure,  $a = 0.929$ ,  $b = 1.033$ ,  $c = 0.817$  (Venturini et al. 1985a; powder X-ray diffraction data). For the experimental details, see Sc-Cr-Ge.

Engel et al. (1984), from X-ray powder diffraction data, characterized the compound Sc<sub>4</sub>Os<sub>7</sub>Ge<sub>6</sub> to be isostructural with U<sub>4</sub>Re<sub>7</sub>Si<sub>6</sub>,  $a = 0.8146$ . The sample was synthesized in the same manner as Sc<sub>4</sub>Ru<sub>7</sub>Ge<sub>6</sub>.

#### 4.1.19. Sc-Ir-Ge

No ternary phase diagram is available for the Sc-Ir-Ge system; however, the formation of two ternary scandium iridium germanides has been reported so far.

From X-ray powder analysis Hovestreydt et al. (1982) reported ScIrGe to crystallize with the TiNiSi-type structure. The crystallographic data were:  $a = 0.6446$ ,  $b = 0.4107$ ,  $c = 0.7482$ . For sample preparation, see Sc-Ru-Ge.

Sc<sub>4</sub>Ir<sub>7</sub>Ge<sub>6</sub> is isotypic with the crystal structure of U<sub>4</sub>Re<sub>7</sub>Si<sub>6</sub>,  $a = 0.8146$  (Engel et al. 1984; X-ray powder diffraction). The details of sample preparation are the same as for Sc<sub>4</sub>Ru<sub>7</sub>Ge<sub>6</sub>.

#### 4.1.20. Sc-Pt-Ge

No phase diagram has been established for the Sc-Pt-Ge system. Only one study on the interaction of scandium with platinum and germanium has been reported. According

to Hovestreydt et al. (1982), ScPtGe was found to be isostructural with the TiNiSi-type structure,  $a=0.6585$ ,  $b=0.4215$ ,  $c=0.7141$  (X-ray powder diffraction). For sample preparation, see Sc–Ru–Ge.

#### 4.1.21. Sc–Au–Ge

Little information exists on the Sc–Au–Ge system; only one ternary germanide has been characterized.

The crystal structure of the ScAuGe compound has been investigated by Pöttgen et al. (1996a) by the X-ray single-crystal method. It was found to crystallize with a LiGaGe type,  $a=0.43082$ ,  $c=0.68458$ . The alloy has been prepared by melting a mixture of the elements in an arc furnace and subsequently annealing at 1070 K.

### 4.2. Y–d element–Ge systems

#### 4.2.1. Y–Cr–Ge

The phase equilibria in the Y–Cr–Ge system were investigated by Bodak and Gladyshevsky (1985) by means of X-ray analysis of alloys which were arc melted and subsequently annealed in evacuated silica tubes at 870 K and finally quenched in water. The isothermal section of the Y–Cr–Ge system at 870 K is presented in fig. 38.

Brabers et al. (1994) reported the existence of a compound  $\text{YCr}_6\text{Ge}_6$  with the  $\text{HfFe}_6\text{Ge}_6$  type ( $a=0.5167$ ,  $c=0.8273$ ; X-ray powder diffraction). The sample was prepared by arc melting and subsequent annealing at 1073 K for three weeks in a sealed tube. This phase is not shown in the 870 K isothermal section of the Y–Cr–Ge system (fig. 38).

Fig. 38. Y–Cr–Ge, isothermal section at 870 K.

#### 4.2.2. *Y-Mn-Ge*

No ternary phase diagram is available for the Y–Mn–Ge system. Two ternary compounds have been reported for yttrium–manganese–germanium combinations.

$\text{YMn}_6\text{Ge}_6$  was found to crystallize in the  $\text{HfFe}_6\text{Ge}_6$ -type structure by Venturini et al. (1992),  $a=0.5233$ ,  $c=0.8153$  (X-ray powder diffraction data). The alloy was synthesized by powder metallurgical reaction in evacuated silica tube at 1073 K for 14 days.

Rossi et al. (1978b) reported on investigation of the crystal structure of the  $\text{YMn}_2\text{Ge}_2$  compound (CeGa<sub>2</sub>Al<sub>2</sub> type,  $a=0.3995$ ,  $c=1.0886$ ; X-ray powder method). The alloy was obtained by melting under argon in an induction furnace and was annealed at 770 K for one week. The metals used were of purity greater than 99.9 mass% for Y, and greater than 99.99 mass% for Mn and Ge.

#### 4.2.3. *Y-Fe-Ge*

No phase diagram has been constructed for the Y–Fe–Ge system; five ternary compounds have been found and characterized by various authors.

$\text{YFe}_6\text{Ge}_6$  was reported to be isotypic with the crystal structure of  $\text{YCo}_6\text{Ge}_6$  with lattice parameters  $a=0.5110$ ,  $c=0.4049$  (Mruz et al. 1984). The sample was prepared by arc melting proper amounts of starting components followed by annealing at 870 K for two weeks. At variance with the data of Mruz et al. (1984),  $\text{YFe}_6\text{Ge}_6$  was found to crystallize with the  $\text{TbFe}_6\text{Sn}_6$  type,  $a=0.8116$ ,  $b=1.7672$ ,  $c=0.5120$ , by Venturini et al. (1992) from X-ray powder diffraction data. The alloy was obtained by powder metallurgical reaction in an evacuated silica tube at 1173 K for two weeks.

Pecharsky et al. (1989) reported  $\text{YFe}_{0.33}\text{Ge}_2$  to crystallize with the CeNiSi<sub>2</sub>-type ( $a=0.4118$ ,  $b=1.5903$ ,  $c=0.4002$ ; X-ray powder analysis). The alloy was arc melted and annealed at 870 K. The purity of the starting materials was greater than 99.9 mass%.

$\text{YFe}_4\text{Ge}_2$  is isotypic with the crystal structure of  $\text{ZrFe}_4\text{Si}_2$  with lattice parameters  $a=0.7314$ ,  $c=0.3864$ , after Fedyna (1988). The alloy was prepared by arc melting the proper amounts of starting components followed by annealing at 870 K for 400 hours.

Oleksyn (1990) investigated the crystal structure of the  $\text{Y}_{117}\text{Fe}_{52}\text{Ge}_{112}$  compound by the X-ray powder method ( $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$  type,  $a=2.8409$ ). The alloy was synthesized by arc melting followed by annealing at 1070 K for 350 h. The starting materials were Y 99.83 mass%, Fe 99.9 mass%, Ge 99.99 mass%.

According to X-ray single-crystal data,  $\text{YFe}_2\text{Ge}_2$  was found to be isostructural with the CeGa<sub>2</sub>Al<sub>2</sub> type, with lattice parameters  $a=0.3961$ ,  $c=1.0421$  (Venturini and Malaman 1996). Samples were prepared from stoichiometric amounts of pure elements. After a first reaction in a silica tube under argon, the mixture was melted in an induction furnace.

#### 4.2.4. *Y-Co-Ge*

The phase diagram of the Y–Co–Ge system has not been established; eight ternary compounds have been identified for yttrium–cobalt–germanium combinations.

Méot-Meyer et al. (1985a) reported the crystal structure of the  $\text{YCo}_{1-x}\text{Ge}_2$ ,  $x=0.55$  (CeNiSi<sub>2</sub> type,  $a=0.4106$ ,  $b=1.612$ ,  $c=0.4026$ ). Samples were prepared by powder

metallurgical reaction and annealed in evacuated silica tube at 1173 K. Pecharsky et al. (1989) investigated the formation and crystal structure of the  $YCo_{1-x}Ge_2$  compound by X-ray powder analysis of arc melted alloys annealed at 870 K. The  $CeNiSi_2$ -type structure was confirmed and in addition, the existence of an extended homogeneity region was observed:  $0.2 < x < 0.9$ ,  $a=0.4067-0.4115$ ,  $b=1.5840-1.6080$ ,  $c=0.3946-0.4019$ .

The crystal structure of  $Y_3Co_4Ge_{13}$  ( $Yb_3Rh_4Sn_{13}$  type,  $a=0.8757$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample which was prepared by heating a compacted mixture of starting materials (Y in pieces, 99.9 mass%; Co and powder Ge, 99.99 mass%) in an evacuated quartz tube at 1073 K.

Bruskov et al. (1986) reported on the single-crystal investigation of  $Y_3Co_4Ge_{13}$  (own structure type,  $a=0.8769$ ). The single crystal was obtained from arc melted and annealed at 870 K alloy.

McCall et al. (1973a) mentioned the existence of the  $YCo_2Ge_2$  compound with the  $CeGa_2Al_2$ -type. Venturini and Malaman (1996) confirmed the crystal structure for the  $YCo_2Ge_2$  compound and established the lattice parameters ( $a=0.39698$ ,  $c=1.0025$ ; X-ray single-crystal data). The sample was prepared in the same manner as  $YFe_2Ge_2$ .

From an X-ray powder analysis of alloy annealed at 1173 K,  $Y_2Co_3Ge_5$  was reported to adopt the  $Lu_2Co_3Si_5$  type structure,  $a=0.9642$ ,  $b=1.180$ ,  $c=0.5707$ ,  $\beta=91.9^\circ$  (Venturini et al. 1986b).

The crystal structure of the  $YCo_6Ge_6$  compound was reported by Buchholz and Schuster (1981) (own structure type,  $a=0.5074$ ,  $c=0.39908$ ). Samples were melted under an argon atmosphere in a corundum crucible at 1073–1273 K.

Gorelenko et al. (1984) reported the crystal structure of  $YCoGe$  ( $TiNiSi$  type,  $a=0.6880$ ,  $b=0.4212$ ,  $c=0.7258$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

$Y_3Co_2Ge_4$  crystallizes with the  $Tb_3Co_2Ge_4$  type structure,  $a=1.0608$ ,  $b=0.8050$ ,  $c=0.4181$ ,  $\gamma=107.80^\circ$ . Samples were prepared by arc melting and annealing at 873 K for 1450 h. The starting materials were: Y (>99.9 mass%), Co (99.99 mass%), Ge (99.999 mass%) (Mruz et al. 1989).

$Y_2CoGe_6$  is isotopic with  $Ce_2CuGe_6$ ,  $a=0.3940$ ,  $b=0.3993$ ,  $c=2.1426$  (Oleksyn et al. 1991; X-ray powder diffraction data). The sample was melted in an arc furnace and annealed at 1070 K in an evacuated quartz capsule for 400 h. The purity of the starting materials was greater than 99.9 mass%.

#### 4.2.5. *Y-Ni-Ge*

Figure 39 represents the isothermal sections of Y-Ni-Ge phase diagram at 1070 K (0–33 at.% Y) and at 670 K (33–100 at.% Y) which were studied by Koterlyn et al. (1988). The isothermal sections were constructed by means of X-ray powder analysis of alloys, which were arc melted and subsequently annealed in evacuated silica tubes for 400 h and finally quenched in water. Starting materials were Y 99.99 mass%, Ni 99.98 mass% and Ge 99.99 mass%.

The ternary phase diagram is characterized by the existence of ten ternary compounds and by the formation of a substitutional exchange of Ge/Ni in the solid solutions

Fig. 39. Y–Ni–Ge, isothermal section at 1070 K (0–33 at.% Y) and at 670 K (33–100 at.% Y).

$Y_2(Ni_{1-x}Ge_x)_{17}$  and  $Y(Ni_{1-x}Ge_x)_5$  for  $0 < x < 0.12$ . This behavior corresponds to the solid solution range of Ge in nickel. Nonstoichiometry and a homogeneity range were observed for  $YNi_{1-x}Ge_2$  ( $0.4 < x < 0.7$ ) (8). The binary compound  $Y_2Ge_3$  dissolves 20 at.% Ni.

$YNi_5Ge_3$  (1) was reported to crystallize with an  $YNi_5Si_3$ -type,  $a=1.9108$ ,  $b=0.3864$ ,  $c=0.6773$  by Fedyna (1988). The alloy, arc melted and annealed at 870 K, was investigated by X-ray powder diffraction analysis. Starting materials were Y 99.83 mass%, Ni 99.99 mass%, Ge 99.99 mass%.

$Y_3Ni_{11}Ge_4$  (2) belongs to the  $Sc_3Ni_{11}Si_4$  type,  $a=0.8319$ ,  $c=0.8821$  after Fedyna (1988). For sample preparation, see the previous paragraph.

The  $YNi_2Ge_2$  (3) compound was found to adopt the  $CeGa_2Al_2$ -type structure,  $a=0.4043$ ,  $c=0.9763$  (Rieger and Parthé 1969b). Venturini and Malaman (1996) confirmed the crystal structure for the  $YNi_2Ge_2$  compound and established the lattice parameters  $a=0.39698$ ,  $c=1.0025$  from X-ray single crystal diffraction. The sample was prepared in the same manner as  $YFe_2Ge_2$ , see Y–Fe–Ge.

$YNiGe_3$  (4) with the  $ScNiSi_3$ -type of structure ( $a=2.1657$ ,  $b=0.4102$ ,  $c=0.4092$ , X-ray powder diffraction analysis) was reported by Bodak et al. (1985). For the details of sample preparation and purity of starting materials, see  $YNi_5Ge_3$ .

$Y_2NiGe_6$  (6) has been found by Oleksyn (1990) from X-ray powder diffraction to be isostructural with  $Ce_2CuGe_6$ -type structure ( $a=0.3956$ ,  $b=2.1265$ ,  $c=0.4007$ ). The sample was prepared by arc melting ingots of the constituting elements and annealing at 1070 K for 700 h. For the purity of starting materials, see  $YNi_5Ge_3$ , above.

Pecharsky et al. (1989) investigated the formation and crystal structure of the

$\text{YNi}_{1-x}\text{Ge}_2$  (8) compound by X-ray powder analysis of arc melted alloys annealed at 870 K (CeNiSi<sub>2</sub> type,  $a = 0.4090\text{--}0.4101$ ,  $b = 1.607\text{--}1.629$ ,  $c = 0.3969\text{--}0.4012$ ). For sample preparation, see  $\text{YFe}_{1-x}\text{Ge}_2$  under Y–Fe–Ge.

Gorelenko et al. (1984) reported the crystal structure of  $\text{YNiGe}$  (8) (TiNiSi type,  $a = 0.6970$ ,  $b = 0.4212$ ,  $c = 0.7258$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

Bodak et al. (1982) reported on the crystal structure of  $\text{Y}_3\text{NiGe}_2$  (10) from X-ray powder diffraction ( $\text{La}_3\text{NiGe}_2$  type,  $a = 1.1304$ ,  $b = 0.4215$ ,  $c = 1.1299$ ). The proper amounts of starting components were arc melted and annealed at 870 K.

The crystal structure of two ternary compounds  $\text{YNiGe}_2$  (5) and  $\text{Y}_{4.75}\text{NiGe}_{4.25}$  (9) has not been determined (Koterlyn et al. 1988).

#### 4.2.6. Y–Cu–Ge

No isothermal section is available for the Y–Cu–Ge system; four ternary compounds have been found and analyzed by different groups of authors.

Rieger and Parthé (1969a) investigated the occurrence of the  $\text{AlB}_2$ -type structure by means of X-ray powder diffraction of arc melted alloys. The data presented were  $\text{YCu}_{1-0.67}\text{Ge}_{1-1.33}$  with  $a = 0.404\text{--}0.4217$ ,  $c = 0.405\text{--}0.3696$ . In variance with the data by Rieger and Parthé (1969a), Iandelli (1993) observed  $\text{YCuGe}$  with the  $\text{CaIn}_2$ -type ( $a = 0.4228$ ,  $c = 0.7325$ , X-ray powder analysis). The alloy was prepared from filings or powders of metals (yttrium 99.7 mass%, copper and germanium 99.99 mass%), which were mixed and sealed in tantalum crucible under argon, melted by induction heating and annealed for 10 days at 1023 K.

$\text{Y}_6\text{Cu}_8\text{Ge}_8$  crystallizes with the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$ -type structure and the lattice parameters are  $a = 1.392$ ,  $b = 0.665$ ,  $c = 0.419$  (Hanel and Nowotny 1970).

Konyk et al. (1988) investigated the crystal structure of  $\text{Y}_2\text{CuGe}_6$  alloy prepared by arc melting under argon and annealed at 870 K in evacuated quartz tube for 720 h. From X-ray powder analysis a  $\text{Ce}_2\text{CuGe}_6$ -type was claimed,  $a = 0.3993$ ,  $b = 0.4108$ ,  $c = 2.0980$ .

Rieger and Parthé (1969b) prepared  $\text{YCu}_2\text{Ge}_2$  with a  $\text{CeGa}_2\text{Al}_2$ -type of structure,  $a = 0.4035$ ,  $c = 1.0303$ .

#### 4.2.7. Y–Nb–Ge

The phase diagram of the Y–Nb–Ge system has not been established. The existence of a compound  $\text{Y}_2\text{Nb}_3\text{Ge}_4$  with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$ -type ( $a = 0.6964$ ,  $b = 1.3572$ ,  $c = 0.7182$ ) was reported by Le Bihan et al. (1996a) from X-ray powder diffraction data of arc melted alloy. The starting materials were: Y and Nb 99.99 mass%, Ge 99.999 mass%.

#### 4.2.8. Y–Mo–Ge

No ternary compounds or solid solutions were found in the Y–Mo–Ge system at 870 K by Bodak and Gladyshevsky (1985) from X-ray powder diffraction of arc melted samples which were annealed at 870 K for three weeks (see fig. 40).

The existence of a compound  $\text{Y}_2\text{Mo}_3\text{Ge}_4$  with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$  type ( $a = 0.6912$ ,  $b = 1.3134$ ,  $c = 0.7067$ ) was reported by Le Bihan et al. (1996b) from X-ray powder diffraction of arc melted alloy. For the purity of the starting materials, see Y–Nb–Ge.

Fig. 40. Y–Mo–Ge, isothermal section at 870 K.

#### 4.2.9. Y–Ru(Rh, Pd)–Ge

The ternary Y–Ru(Rh, Pd)–Ge systems have been studied only with respect to the formation of compounds with specific composition and structure. Their crystallographic characteristics are listed in table 10.

Table 10  
Crystallographic data for the ternary Y–Ru(Rh, Pd)–Ge compounds

4.2.10. *Y–Ag–Ge*

No phase diagram is available for the Y–Ag–Ge system. Protsyk (1994) reported the existence of the  $\text{YAg}_{0.33}\text{Ge}_{1.67}$  compound with  $\alpha\text{-ThSi}_2$  type ( $a = 0.4070$ ,  $c = 1.3710$ ; X-ray powder diffraction data). Samples were arc melted and annealed at 870 K for 400 hours.

Gibson et al. (1996) investigated the crystal structure of the YAgGe compound (ZrNiAl type,  $a = 0.71180$ ,  $c = 0.41968$ ). The sample was prepared from the elements by arc melting and annealing at 970 K for ten days.

4.2.11. *Y–Os(Ir,Pt)–Ge*

The ternary Y–Os(Ir,Pt)–Ge systems have been studied only with respect to the formation of compounds with specific composition and structure. Their crystallographic data are presented in table 11.

Table 11  
Crystallographic data for the ternary Y–Os(Ir,Pt)–Ge compounds

4.2.12. *Y–Au–Ge*

No ternary phase diagram is available for the Y–Au–Ge system, however, a ternary compound of yttrium with gold and germanium with the 1:1:1 stoichiometric ratio has been identified and studied by means of X-ray and metallographic analyses by Rossi et al. (1992). It was found to adopt the LiGaGe type with lattice parameters  $a = 0.4408$ ,  $c = 0.7307$ . The sample was prepared by melting the metals (purity around 99.9 mass% for

yttrium and 99.99 mass% for gold and germanium) in an induction furnace and annealing at 1070 K for one week.

### 4.3. *La–d element–Ge systems*

#### 4.3.1. *La–Mn–Ge*

No phase diagram is available for the system La–Mn–Ge, however, two ternary compounds have been observed and characterized.

The  $\text{LaMn}_2\text{Ge}_2$  compound has been prepared and studied by Rossi et al. (1978b). It was found to be of  $\text{CeGa}_2\text{Al}_2$  type with lattice parameters  $a = 0.4108$ ,  $c = 1.0685$ . The alloy was obtained by melting under argon atmosphere in an induction furnace. The sample was then annealed at 500°C for one week. The lanthanum used was of a purity greater than 99.9 mass%, for manganese and germanium the purity was greater than 99.99 mass%.

The  $\text{LaMnGe}$  compound with  $\text{PbFCl}$ -type was observed by Welter et al. (1995);  $a = 0.4254$ ,  $c = 0.7425$ . The compound was prepared from commercially available high purity elements. Compacted pellet of stoichiometric mixture was sealed under argon (100 mmHg) in silica tube which was heated at 1273 K as a preliminary homogenization treatment and then melted in an induction furnace. The resulting ingot was annealed for 2 weeks at 1173 K.

#### 4.3.2. *La–Fe–Ge*

No phase diagram is available at present for the La–Fe–Ge system; the formation of three ternary germanides has been reported by various authors.

The  $\text{LaFe}_{0.67}\text{Ge}_{1.33}$  compound was found to adopt the  $\text{AlB}_2$ -type structure ( $a = 0.4223$ ,  $c = 0.4316$ ; X-ray powder diffraction) (Felner and Schieber 1973). The sample was prepared by melting elements together (lanthanum 99.9 mass%, Ge 99.99 mass%, Fe 99.95 mass%). The metals were mixed and heated in an alumina crucible in an induction furnace under the protective atmosphere of argon. The sample was homogenized by annealing at 1870 K for about 30 min.

The  $\text{LaFe}_2\text{Ge}_2$  compound was initially investigated by Rossi et al. (1978a) ( $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.4110$ ,  $c = 1.0581$ ) by means of X-ray diffraction. Bara et al. (1990) confirmed the crystal structure of the  $\text{LaFe}_2\text{Ge}_2$  compound ( $a = 0.4128$ ,  $c = 1.0602$ ; X-ray powder diffraction) from an arc melted sample, annealed for 1 week at 1073 K. The purity of the starting elements was La, 4N; Fe, 3N; Ge, 5N.

Francois et al. (1990) investigated the occurrence of the  $\text{CeNiSi}_2$  type for lanthanum–iron–germanium combinations from the alloys annealed at 1173 K ( $\text{LaFe}_{0.60-0.69}\text{Ge}_2$ ;  $a = 0.4347-0.4359$ ,  $b = 1.683-1.679$ ,  $c = 0.4210-0.4225$ ).

#### 4.3.3. *La–Co–Ge*

The equilibrium phase diagram for the La–Co–Ge system has not been reported. Lanthanum–cobalt–germanium combinations have been investigated only with respect to

the formation and crystal structure of compounds with various stoichiometries. To date five compounds have been identified.

Méot-Meyer et al. (1985a) reported the crystal structure of  $\text{LaCo}_{0.96}\text{Ge}_2$  (CeNiSi<sub>2</sub> type,  $a=0.4309$ ,  $b=1.688$ ,  $c=0.4238$ ). The sample was prepared by powder metallurgical reaction and annealed in evacuated silica tube at 1173 K. Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{LaCo}_{1-x}\text{Ge}_2$  compound by X-ray powder analysis of arc melted alloy annealed at 870 K. The CeNiSi<sub>2</sub>-type structure was confirmed for the sample of stoichiometric composition ( $a=0.4335$ ,  $b=1.6945$ ,  $c=0.4279$ ).

McCall et al. (1973b) investigated the crystal structure of the  $\text{LaCo}_2\text{Ge}_2$  compound (BaAl<sub>4</sub> type,  $a=0.4123$ ,  $c=1.0277$ ; X-ray powder diffraction). The sample was melted in an induction furnace. Starting components were Co, Ge (5N) and La (3N).

The crystal structure of  $\text{LaCoGe}_3$  (BaNiSn<sub>3</sub> type,  $a=0.4350$ ,  $c=0.9865$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample which was prepared by heating a compacted mixture of starting materials (La in pieces, 99.9 mass%; Co and powder Ge, 99.99 mass%) in an evacuated quartz tube at 1073 K. Later the crystal structure of  $\text{LaCoGe}_3$  compound was confirmed by Pecharsky et al. (1993) by means of metallography and room-temperature X-ray powder diffractometry. The crystal structure has been established and lattice parameters have been measured (BaNiSn<sub>3</sub> type,  $a=0.43497$ ,  $c=0.98679$ ). The alloy was prepared by arc melting pieces of the metals under an argon atmosphere and then heat treating it at 1173 K for 7 days in a helium-filled quartz tube. The starting metals were La 99.79 mass%, Co and Ge >99.999 mass%.

The  $\text{LaCoGe}$  compound with PbFCl-type structure was observed by Welter et al. (1993a);  $a=0.4194$ ,  $c=0.7028$ . The compound was prepared from commercially available high-purity elements. A compacted pellet of stoichiometric mixture was sealed under argon (100 mmHg) in a silica tube which was heated at 1173 K as a preliminary homogenization treatment and then melted in an induction furnace. The resulting ingot was annealed for 2 weeks at 1173 K.

The crystal structure of the  $\text{La}_6\text{Co}_{13}\text{Ge}$  compound was reported by Weitzer et al. (1990) (Nd<sub>6</sub>Fe<sub>13</sub>Si type,  $a=0.80620$ ,  $c=2.29224$ ). The sample was melted under argon and annealed at 1073 K for 5 days. Starting materials were commercially available high-purity elements.

#### 4.3.4. *La-Ni-Ge*

No phase diagram is available for the La-Ni-Ge system, but nine ternary phases have been identified.

Bodak et al. (1982) investigated the crystal structure of the  $\text{La}_3\text{NiGe}_2$  compound (own structure type,  $a=1.2041$ ,  $b=0.4358$ ,  $c=1.1871$ ) by the single-crystal diffraction method. For sample preparation and purity of starting elements, see Y-Ni-Ge.

The  $\text{LaNi}_2\text{Ge}_2$  compound was found to adopt the CeGa<sub>2</sub>Al<sub>2</sub>-type structure,  $a=0.4187$ ,  $c=0.9918$  (Rieger and Parthé 1969b).

Pecharsky et al. (1989) reported the crystal structure of the  $\text{LaNiGe}_2$  ( $\text{CeNiSi}_2$  type,  $a = 0.4314$ ,  $b = 1.688$ ,  $c = 0.4235$ ) from X-ray powder analysis of arc melted alloy annealed at 870 K. The stoichiometric composition and crystal structure type were confirmed by Francois et al. (1990). For sample preparation, see La–Fe–Ge.

Gladyshevsky and Bodak (1965) determined the  $\text{AlB}_2$ -type structure for the compound  $\text{LaNi}_{0.67-0.5}\text{Ge}_{1.33-1.5}$ ,  $a = 0.4202-0.4193$ ,  $c = 0.4306-0.4336$  (X-ray powder diffraction).

Bruskov (1984) investigated the crystal structure for the compounds  $\text{La}_3\text{Ni}_4\text{Ge}_4$  ( $\text{U}_3\text{Ni}_4\text{Si}_4$ -type structure,  $a = 0.4223$ ,  $b = 0.4230$ ,  $c = 2.4156$ ; X-ray single-crystal method);  $\text{La}_{11}\text{Ni}_4\text{Ge}_6$  (own structure type,  $a = 1.8637$ ,  $b = 0.4384$ ,  $c = 1.4191$ ,  $\beta = 106,13^\circ$ ; X-ray single-crystal method);  $\text{La}_8\text{NiGe}_5$  (own structure type,  $a = 1.5586$ ,  $b = 1.8384$ ,  $c = 1.1351$ ; X-ray single-crystal method);  $\text{La}(\text{Ni}_{0.82}\text{Ge}_{0.18})_{13}$  ( $\text{NaZn}_{13}$  type,  $a = 1.1371$ ); and  $\text{La}_2\text{NiGe}$  (own structure type,  $a = 0.7947$ ,  $c = 1.4262$ ; X-ray single-crystal method). For sample preparation, see Y–Ni–Ge.

#### 4.3.5. La–Cu–Ge

No phase diagram is available for the system La–Cu–Ge, however the crystallographic characteristics for a series of ternary compounds are presented in the literature.

Rieger and Parthé (1969a) investigated the occurrence of the  $\text{AlB}_2$ -type structure by means of X-ray powder diffraction of arc melted alloys. The data presented were  $\text{LaCu}_{1-0.67}\text{Ge}_{1-1.33}$  with  $a = 0.4323-0.4223$ ,  $c = 0.4050-0.4322$ . Iandelli (1993) confirmed  $\text{AlB}_2$ -type ( $a = 0.4335$ ,  $c = 0.4040$ , X-ray powder analysis) from the LaCuGe alloy which was prepared from filings or powders of the metals (La 99.7 mass%, Co and Ge 99.99 mass%), sealed in a tantalum crucible under argon followed by melting in an induction furnace; afterwards the sample was annealed for 10 days at 1023 K.

Konyk et al. (1988) reported on the crystal structure of  $\text{La}_2\text{CuGe}_6$  alloy prepared by arc melting under argon and annealed at 870 K in an evacuated quartz tube for 720 h. From X-ray powder analysis a  $\text{Ce}_2\text{CuGe}_6$ -type was claimed,  $a = 0.4100$ ,  $b = 0.4258$ ,  $c = 2.1838$ .

Rieger and Parthé (1969b) prepared  $\text{LaCu}_2\text{Ge}_2$  with the  $\text{CeGa}_2\text{Al}_2$ -type of structure,  $a = 0.4265$ ,  $c = 1.0170$ .

Francois et al. (1990) reported the crystal structure of the  $\text{LaCu}_{0.82-0.92}\text{Ge}_2$  ( $\text{CeNiSi}_2$  type,  $a = 0.4335-0.4333$ ,  $b = 1.740-1.740$ ,  $c = 0.4175-0.4193$ ). For sample preparation, see La–Fe–Ge.

#### 4.3.6. La–Zn–Ge

No isothermal section is available for the ternary La–Zn–Ge system, however one ternary compound was observed and characterized by Rossi and Ferro (1996).  $\text{LaZn}_{1.5}\text{Ge}_{0.5}$  was found to crystallize with an  $\text{AlB}_2$  type,  $a = 0.4471$ ,  $c = 0.4032$  from X-ray powder diffraction of melted in an induction furnace alloy which was afterwards annealed at 1070 K for one week. An electronic micrographic examination as well as microprobe analysis were carried out. The metals employed in the synthesis of sample had a nominal purity of 99.9 mass% for La, and 99.999 mass% for other metals.

#### 4.3.7. *La–Ru–Ge*

The phase diagram for the La–Ru–Ge system is not yet available, however several groups of authors investigated lanthanum–ruthenium–germanium combinations with respect to the formation and crystal structure of compounds.

Venturini et al. (1985b) reported on the X-ray powder diffraction study of the LaRuGe<sub>3</sub> compound from the sample which was prepared by heating a mixture of the starting components (La 3N, Ru 4N, Ge 4N) in evacuated quartz tube at 1073 K. The crystal structure was found to adopt the BaNiSn<sub>3</sub> type,  $a=0.4414$ ,  $c=1.0123$ .

Venturini and Malaman (1996) reported on the single crystal refinement of the CeGa<sub>2</sub>Al<sub>2</sub>-type structure of the LaRu<sub>2</sub>Ge<sub>2</sub> composition,  $a=0.42866$ ,  $c=1.0121$ . Samples were prepared from stoichiometric amounts of pure elements. After a first reaction in a silica tube under argon, the mixture was melted in an induction furnace.

La<sub>2</sub>Ru<sub>3</sub>Ge<sub>5</sub> was found to crystallize with U<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub>-type ( $a=1.00108$ ,  $b=1.2496$ ,  $c=0.59256$ , X-ray single-crystal diffraction method) by Venturini et al. (1989b).

The crystal structure of the LaRuGe compound was investigated by Welter et al. (1993b). It was found to adopt the PbFCl-type structure,  $a=0.4294$ ,  $c=0.7019$  (X-ray powder diffraction). The compound was prepared from commercially available high purity elements. A compact of a stoichiometric mixture was heated in sealed under argon silica tube at 1173 K for preliminary homogenization and then melted in an induction furnace.

La<sub>3</sub>Ru<sub>2</sub>Ge<sub>2</sub> compound was found to crystallize with La<sub>3</sub>Ni<sub>2</sub>Ga<sub>2</sub>-type ( $a=0.5787$ ,  $b=0.7946$ ,  $c=1.3729$ , X-ray powder diffraction) from the arc melted and annealed at 870 K sample (Bodak et al. 1989a).

#### 4.3.8. *La–Rh–Ge*

Venturini et al. (1985b) reported on the X-ray powder diffraction study of the LaRhGe<sub>3</sub> compound from the sample which was prepared by heating the mixture of starting components (La 3N, Rh 4N, Ge 4N) in evacuated quartz tube at 1073 K. The crystal structure was found to adopt the BaNiSn<sub>3</sub> type,  $a=0.4419$ ,  $c=1.0046$ .

Venturini and Malaman (1996) reported on the single crystal refinement of the CeGa<sub>2</sub>Al<sub>2</sub>-type structure germanide of the LaRh<sub>2</sub>Ge<sub>2</sub> composition,  $a=0.4174$ ,  $c=1.0519$ . Samples were prepared from stoichiometric amounts of pure elements. After a first reaction in a silica tube under argon, the mixture was melted in an induction furnace.

La<sub>2</sub>Rh<sub>3</sub>Ge<sub>5</sub> was found to crystallize with U<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub>-type structure ( $a=1.0135$ ,  $b=1.2177$ ,  $c=0.60410$ , X-ray single-crystal diffraction method) by Venturini et al. (1989a).

Gladyshevsky et al. (1991a) reported on the crystal structure for the La<sub>3</sub>Rh<sub>2</sub>Ge<sub>2</sub> compound (La<sub>3</sub>Ni<sub>2</sub>Ge<sub>2</sub> type,  $a=0.5766$ ,  $b=0.8195$ ,  $c=1.3609$ ; X-ray powder diffraction). The alloy was prepared by arc melting and annealing at 1070 K.

Francois et al. (1990) reported the crystal structure of LaRhGe<sub>2</sub> (CeNiSi<sub>2</sub> type,  $a=0.4375$ ,  $b=1.715$ ,  $c=0.4367$ ). For sample preparation, see LaFeGe<sub>2</sub> under La–Fe–Ge.

La<sub>3</sub>Rh<sub>4</sub>Ge<sub>4</sub> crystallizes with U<sub>3</sub>Ni<sub>4</sub>Si<sub>4</sub> type,  $a=0.4174$ ,  $b=0.4241$ ,  $c=2.5234$  (Parthé and Chabot 1984).

#### 4.3.9. La–Pd–Ge

Phase relations have not been established for the La–Pd–Ge system; formation and crystal structure for five ternary compounds have been reported so far.

Venturini and Malaman (1996) reported on the single crystal refinement of the  $\text{CeGa}_2\text{Al}_2$ -type structure germanide of the  $\text{LaPd}_2\text{Ge}_2$  composition,  $a=0.43669$ ,  $c=1.0027$ . For the details of synthesis, see  $\text{LaRu}_2\text{Ge}_2$  under La–Ru–Ge.

Francois et al. (1990) reported the crystal structure of the  $\text{LaPdGe}_2$  ( $\text{CeNiSi}_2$  type,  $a=0.4379$ ,  $b=1.737$ ,  $c=0.4382$ ). For sample preparation, see  $\text{LaFeGe}_2$  under La–Ru–Ge.

According to an X-ray powder diffraction analysis Hovestreydt et al. (1982) reported the compound  $\text{LaPdGe}$  adopted the  $\text{KHg}_2$ -type structure,  $a=0.4518$ ,  $b=0.7409$ ,  $c=0.7740$ . An alloy was arc melted under argon and annealed at 1270 K for 1–2 weeks. Starting materials were La (3N), Pd (4N) and Ge (5N).

The crystal structure of the compound  $\text{LaPd}_2\text{Ge}$  was found to be of the  $\text{YPd}_2\text{Si}$  type ( $a=0.7711$ ,  $b=0.6972$ ,  $c=0.5828$ ; X-ray powder diffraction) by Jorda et al. (1983). The sample was obtained by induction heating of pressed powder compacts in a levitation coil under an argon atmosphere pressure of 4 atm. After the rapid reaction in the liquid state the molten sample was dropped into a boron nitride crucible. Then alloy was annealed in evacuated quartz tube for 10 days at 1173 K. Starting materials were Pd 99.99 mass%, Ge, specpure quality, La 99.9 mass%.

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{La}_2\text{PdGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$  type structure,  $a=0.4211$ ,  $b=0.4110$ ,  $c=2.2265$ . The sample was synthesized by argon arc melting followed by a heat treatment at 870 K for 150 hours. Starting materials used were obtained from Johnson & Matthey, UK (99.9 mass%).

#### 4.3.10. La–Ag–Ge

A systematic study of the La–Ag–Ge system at 770 K was performed by Protsyk (1994). The samples were prepared by arc melting under argon and annealed in evacuated quartz ampoules at 770 K for 500 hours. Starting materials were La 99.98 mass%, Ag 99.9 mass% and Ge 99.99 mass%. Phase relations are characterized by the formation of four ternary compounds (see fig. 41).

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{La}_2\text{AgGe}_6$  (2) compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.43409$ ,  $b=0.41598$ ,  $c=2.1901$ . For the experimental details, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge.

$\text{LaAgGe}$  (3) with the  $\text{LiGaGe}$ -type of structure ( $a=0.45587$ ,  $c=0.78969$ ; X-ray powder diffraction data) was observed by Pecharsky et al. (1991) from arc melted alloy heat-treated at 1023 K in a helium-filled sealed quartz tube for one week. The lanthanum was 99.79 mass% pure; the silver was 99.99 mass% pure and the germanium was 99.999 mass% pure.

The existence of  $\text{LaAg}_2\text{Ge}_2$  (1) ( $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4358$ ,  $c=1.0982$ ) and  $\text{LaAg}_{0.8}\text{Ge}_{1.2}$  (4) ( $\text{AlB}_2$  type,  $a=0.4366$ ,  $c=0.4280$ ) was reported by Protsyk (1994) from X-ray powder diffraction of alloy annealed at 773 K.

Fig. 41. La–Ag–Ge, isothermal section at 770 K.

#### 4.3.11. La–Os–Ge

Little information exists on the interaction of lanthanum and osmium with germanium. One ternary compound was observed and characterized within the La–Os–Ge system. The crystal structure of the LaOsGe<sub>3</sub> compound (BaNiSn<sub>3</sub> type,  $a=0.4441$ ,  $c=1.0124$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from the sample which was prepared by heating a compacted mixture of the starting materials (La in pieces, 99.9 mass%; Os and powder Ge, 99.99 mass%) in an evacuated quartz tube at 1073 K.

#### 4.3.12. La–Ir–Ge

No ternary phase diagram has been established for the La–Ir–Ge system, however five ternary compounds have been characterized.

Venturini et al. (1985b) reported on the X-ray powder diffraction study of the LaIrGe<sub>3</sub> compound from a sample prepared by heating a mixture of starting components (La 3N, Ir 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to be BaNiSn<sub>3</sub> type,  $a=0.4428$ ,  $c=1.0042$ .

La<sub>2</sub>Ir<sub>3</sub>Ge<sub>5</sub> was found to crystallize with U<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub>-type structure ( $a=1.0218$ ,  $b=1.2028$ ,  $c=0.6091$ , X-ray single-crystal diffraction method) by Venturini et al. (1989b).

Francois et al. (1990) reported the crystal structure of LaIrGe<sub>2</sub> (CeNiSi<sub>2</sub> type,  $a=0.4389$ ,  $b=1.716$ ,  $c=0.4389$ ). For sample preparation, see LaFeGe<sub>2</sub> under La–Fe–Ge.

According to X-ray powder diffraction analysis reported by Hovestreydt et al. (1982) the compound LaIrGe adopted the LaPtSi-type structure,  $a=0.43166$ ,  $c=1.4430$ . The alloy was arc melted under argon and annealed at 1270 K for 1–2 weeks. Starting materials were La (3N), Ir (4N) and Ge (5N).

$\text{LaIr}_2\text{Ge}_2$  is isotypic with the crystal structure of  $\text{CaBe}_2\text{Ge}_2$  with lattice parameters  $a=0.4273$ ,  $c=1.0134$  (Francois et al. 1985).

Verniere et al. (1995) observed the existence of the  $\text{La}_4\text{Ir}_{13}\text{Ge}_9$  compound with  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type structure from an arc melted sample annealed at 1170 K for 8 days. No lattice parameters were given. The purity of the starting elements was 3N for the lanthanum, 4N for the iridium and 6N for the germanium.

#### 4.3.13. *La-Pt-Ge*

Francois et al. (1990) reported the crystal structure of  $\text{LaPtGe}_2$  (CeNiSi<sub>2</sub> type,  $a=0.4404$ ,  $b=1.720$ ,  $c=0.4404$ ). For sample preparation, see *La-Fe-Ge*.

According to X-ray powder diffraction analysis reported by Hovestreydt et al. (1982) the compound  $\text{LaPtGe}$  adopted the  $\text{LaPtSi}$ -type structure,  $a=0.4266$ ,  $c=0.14970$ . The alloy was arc melted under argon and annealed at 1270 K for 1–2 weeks. Starting materials were La (3N), Pt (4N) and Ge (5N).

The existence of the  $\text{LaPt}_2\text{Ge}_2$  compound (CeGa<sub>2</sub>Al<sub>2</sub> type,  $a=0.4412$ ,  $c=0.9923$ ) was reported by Rossi et al. (1979) from X-ray powder diffraction of the induction melted sample which was annealed at 773 K for 1 week. Starting components were La (3N), Pt (4N) and Ge (4N). Venturini et al. (1989a) investigated the crystal structure of  $\text{LaPt}_2\text{Ge}_2$  from an arc melted sample annealed at 1273 K for 5 days. The crystal structure was found to belong to a new structure type,  $a=0.4301$ ,  $b=0.4346$ ,  $c=0.9682$ ,  $\beta=91.26^\circ$ . Starting materials were La (3N), Pt (4N) and Ge (4N).

#### 4.3.14. *La-Au-Ge*

No ternary phase diagram exists for the *La-Au-Ge* system, however, a ternary compound of lanthanum with gold and germanium of the 1:1:1 stoichiometric ratio has been identified and studied by means of X-ray and metallographic analyses by Rossi et al. (1992). The  $\text{LaAuGe}$  compound was found to adopt the  $\text{LiGaGe}$ -type structure with lattice parameters  $a=0.4463$ ,  $c=0.8169$ . The sample was prepared by melting the metals (around 99.9 mass% for lanthanum and 99.99 mass% for gold and germanium) in an induction furnace and annealing at 1070 K for one week.

### 4.4. *Ce-d element-Ge systems*

#### 4.4.1. *Ce-Mn-Ge*

The phase equilibria in the *Ce-Mn-Ge* system (fig. 42) have been investigated by Konyk (1989) by means of X-ray analysis of 104 alloys which were arc melted and subsequently annealed in evacuated silica tubes for 400–720 h at 670 K and finally quenched in water. Starting materials were Ce 99.85 mass%, Mn 99.91 mass% and Ge 99.99 mass%. The existence of one ternary compound was confirmed [ $\text{CeMn}_2\text{Ge}_2$  (1)] and the formation of three new ternary cerium manganese germanides was observed [ $\text{Ce}_2\text{MnGe}_6$  (2),  $\text{Ce}_2\text{MnGe}_5$  (3) and  $\text{CeMnGe}$  (4)].

Fig. 42. Ce-Mn-Ge, isothermal section at 670 K.

The formation of the  $\text{CeMn}_2\text{Ge}_2$  compound ( $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4144$ ,  $c=1.0970$ ; for sample preparation, see  $\text{LaMn}_2\text{Ge}_2$ ) was reported in an early investigation of the ternary rare-earth germanides with the stoichiometric ratio 1:2:2 by Rossi et al. (1978b). Crystallographic characteristics after Konyk (1989) are as follows:  $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4135$ ,  $c=1.0928$ .

The  $\text{Ce}_2\text{MnGe}_6$  compound crystallizes with the  $\text{Ce}_2\text{CuGe}_6$ -type of structure with lattice parameters  $a=0.4103$ ,  $b=0.4342$ ,  $c=2.188$  (Konyk 1989).

$\text{Ce}_2\text{MnGe}_5$  was reported by Konyk (1989) to crystallize with a new structure type,  $a=0.4308$ ,  $b=0.4170$ ,  $c=2.1134$  (X-ray powder diffraction data).

$\text{CeMnGe}$  was found to be isostructural with the  $\text{PbFCl}$  type,  $a=0.4235$ ,  $c=0.7393$  (Konyk 1989). The crystal structure of  $\text{CeMnGe}$  was recently confirmed by Welter et al. (1995) ( $\text{PbFCl}$  type,  $a=0.4235$ ,  $c=0.7386$ ; powder X-ray diffraction). For details of the experimental procedure, see  $\text{LaMnGe}$ .

#### 4.4.2. Ce-Fe-Ge

The isothermal sections for the Ce-Fe-Ge phase diagram at 870 K were reported by Salamakha et al. (1996a) from a combined X-ray and micrography examination of 139 alloys. For details of sample preparation, see Ce-Mn-Ge. The microstructure of the alloys was revealed by etching in dilute solutions of HCl and HF. Starting materials were Ce 99.85 mass%, Fe 99.90 mass%, Ge 99.99 mass%.

The phase relations are characterized by the formation of seven ternary compounds (fig. 43); the crystal structure has been determined for three of these. Mutual solid solubilities of the binary compounds have been found to be insignificantly small. Crystallographic characteristics for these ternary compounds are summarized in table 12.

Fig. 43. Ce–Fe–Ge, isothermal sections at 870 K (0–50 at.% Ce) and at 670 K (50–100 at.% Ce).

#### 4.4.3. Ce–Co–Ge

Phase equilibria in the Ce–Co–Ge system have been determined by Konyk (1989) by means of powder X-ray and micrographic analyses of 160 ternary alloys at 870 K (0–50 at.% Ce) and at 670 K (50–100 at.% Ce) (fig. 44). The phase relations are characterized by the formation of eleven ternary compounds and by the existence of two substitutional solid solution ranges: Ge in CeCo<sub>5</sub> (12 at.%) and Ge in Ce<sub>2</sub>Co<sub>17</sub> (10 at.%). For sample preparation, see Ce–Mn–Ge. The purity of the starting materials was Ce 99.85 mass%, Co 99.90 mass%, Ge 99.99 mass%.

Crystallographic data for the ternary compounds are summarized in table 13.

Fig. 44. Ce–Co–Ge, isothermal sections at 870 K (0–50 at.% Ce) and at 670 (50–100 at.% Ce).

Fig. 45. Ce–Ni–Ge, isothermal sections at 870 K (0–50 at.% Ce) and at 670 K (50–100 at.% Ce).

#### 4.4.4. Ce–Ni–Ge

Information about the phase equilibria in the Ce–Ni–Ge system is due to the work of Salamakha et al. (1996b) who employed X-ray phase analysis of 227 alloys which were arc melted and annealed at 870 K (0–50 at.% Ce) and 670 K (50–100 at.% Ce) in evacuated quartz tubes for two weeks (fig. 45). Twenty ternary compounds were found and characterized. A large homogeneity range was observed for the CeNi<sub>5</sub> compound by the same authors; the maximum concentration of Ge in Ce(Ni,Ge)<sub>5</sub> solid solution was indicated as 15 at.%.

Crystallographic information on the ternary compounds is summarized in table 14 (overleaf).

One more compound was observed by Belsky et al. (1987) in arc melted alloys, Ce<sub>5</sub>NiGe<sub>2</sub>. A new structure type was reported with lattice parameters  $a=1.1760$ ,  $c=0.6429$ .

#### 4.4.5. Ce–Cu–Ge

Salamakha et al. (1996c) were the first to derive the phase equilibria in an isothermal section at 870 K, employing room-temperature X-ray powder diffraction analysis. Alloys were synthesized by arc melting proper amounts of the constituent elements (Ce 99.85 mass%, Cu 99.99 mass%, Ge 99.99 mass%) under high purity argon on a water cooled copper hearth. Finally alloys were annealed at 870 K in evacuated quartz tubes for two weeks and quenched in water. Phase-field distributions are characterized by existence of eight ternary compounds and one solid solution originating at CeGe<sub>2-x</sub>. The solid-solution limit was established as 10 at.% Cu. The isothermal section of the Ce–Cu–Ge system at 870 K is presented in fig. 46.

Table 14

Rieger and Parthé (1969a) investigated the occurrence of the AlB<sub>2</sub>-type structure by means of X-ray powder diffraction of arc melted alloys. The data presented were CeCu<sub>1–0.67</sub>Ge<sub>1–1.33</sub> with  $a = 0.4296–0.4197$ ,  $c = 0.3988–0.4215$ . Salamakha et al. (1996c) reported on the existence of two compounds with AlB<sub>2</sub>-type within the Ce–Cu–Ge system at 870 K: CeCuGe (5) ( $a = 0.4316$ ,  $c = 0.3967$ ) and CeCu<sub>0.6–0.8</sub>Ge<sub>1.4–1.2</sub> (6) ( $a = 0.4214–0.4188$ ,  $c = 0.4206–0.4264$ ). Iandelli (1993) confirmed AlB<sub>2</sub>-type ( $a = 0.4308$ ,  $c = 0.3966$ , X-ray powder analysis) from an alloy of the stoichiometric composition which was prepared from a mixture of filings or powders of the metals (cerium 99.7 mass%, copper and germanium 99.99 mass%) which were sealed in tantalum crucibles under argon followed by melting in an induction furnace; afterwards the sample was annealed for 10 days at 1023 K.

Konyk et al. (1988) reported on the crystal structure of Ce<sub>2</sub>CuGe<sub>6</sub> (2) alloy prepared by arc melting under argon and annealed at 870 K in an evacuated quartz tube for 720 h. From X-ray powder diffraction analysis a new structure type was suggested,  $a = 0.40756$ ,  $b =$

Fig. 46. Ce–Cu–Ge, isothermal sections at 870 K (0–50 at.% Ce) and at 670 K (50–100 at.% Ce).

0.42152,  $c=2.15408$ . The crystal structure was confirmed later by Sologub et al. (1995a),  $a=0.42116$ ,  $b=0.40725$ ,  $c=2.1584$  (X-ray powder analysis).

Rieger and Parthé (1969b) prepared  $\text{CeCu}_2\text{Ge}_2$  (1) with the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4172$ ,  $c=1.0212$ .

Francois et al. (1990) reported the crystal structure of  $\text{CeCu}_{0.86}\text{Ge}_2$  (4) (CeNiSi<sub>2</sub> type,  $a=0.4276$ ,  $b=1.729$ ,  $c=0.4145$ ). For sample preparation, see LaFeGe<sub>2</sub>.

The  $\text{Ce}_2\text{Cu}_3\text{Ge}_3$  compound (3) was found to crystallize with a new structure type,  $a=0.41680$ ,  $b=1.7409$ ,  $c=0.42108$ , X-ray powder data (Konyk 1988). For sample preparation, see Ce–Cu–Ge.

Salamakha et al. (1996c) reported the existence of two cerium copper germanides of unknown structure,  $\text{Ce}_{0.60}\text{Cu}_{0.25}\text{Ge}_{0.15}$  (7) and  $\text{Ce}_{0.60}\text{Cu}_{0.05}\text{Ge}_{0.35}$  (8), from X-ray powder diffraction of the alloys which were prepared in the same manner as discussed above.

#### 4.4.6. Ce–Zn–Ge

The isothermal section of the equilibrium phase diagram of the Ce–Zn–Ge system at 470 K has been investigated by Opainych (1996) by X-ray powder diffraction analysis. Samples were prepared by argon arc melting from ingots of the high-purity elements (Ce 99.97 mass%, Zn 99.98 mass%, Ge 99.99 mass%) under a pressure of 1.1 atm. Weight losses due to vaporization while melting were compensated beforehand by extra amounts of Zn (about 0.5 mass%). The arc melted buttons were annealed at 470 K for 1500 hours in evacuated quartz tubes and finally quenched by submerging the capsules into cold water.

The phase relations after Opainych (1996) are characterized by the formation of eight ternary compounds (fig. 47). The solid solubility of the third component in the Ce–Zn and Ce–Ge binary compounds has been found to be negligible.

Fig. 47. Ce–Zn–Ge, isothermal section at 470 K.

The  $\text{Ce}_4\text{Zn}_8\text{Ge}_{11-x}$  (2) compound was found to crystallize in an own structure type with lattice parameters  $a=0.59468$ ,  $c=2.4740$  (Opainych 1996; X-ray single-crystal analysis). For sample preparation, see above.

Opainych (1996) reported on the investigation of  $\text{Ce}_2\text{Zn}_{15}\text{Ge}_2$  ( $\text{Ce}_2\text{Al}_2\text{Co}_{15}$  type,  $a=0.9021$ ,  $c=1.3787$ ) (1),  $\text{CeZn}_{1.8}\text{Ge}_{1.2}$  ( $\text{AuCu}_3$  type,  $a=0.5420$ ) (3) and  $\text{Ce}(\text{Zn},\text{Ge})_2$  ( $\alpha\text{-ThSi}_2$  type,  $a=0.4231$ ,  $c=1.4219$ ) (5) from X-ray powder analysis of arc melted alloys annealed at 470 K.

The existence of four ternary phases with unknown structure has been observed by Opainych (1996) in the course of investigating the isothermal section of the Ce–Zn–Ge system at 470 K. They exist at the following compositions:  $\sim\text{Ce}_7\text{Zn}_8\text{Ge}_5$  (4),  $\sim\text{Ce}_2\text{Zn}_2\text{Ge}$  (6),  $\sim\text{Ce}_9\text{Zn}_3\text{Ge}_8$  (7) and  $\sim\text{Ce}_6\text{Zn}_3\text{Ge}$  (8).

One more ternary compound which was not observed in the course of phase-equilibrium studies, was characterized by Rossi and Ferro (1996).  $\text{CeZn}_{1.5}\text{Ge}_{0.5}$  was found to be isotypic with an  $\text{AlB}_2$  type,  $a=0.4447$ ,  $c=0.3924$  from X-ray powder diffraction of an induction melted alloy which was afterwards annealed at 1070 K for one week. An electronic micrographic examination as well as microprobe microanalysis were carried out. The metals employed in the synthesis of samples had a nominal purity of 99.9 mass% for cerium, and 99.999 mass% for other metals.

#### 4.4.7. Ce–Ru–Ge

The phase equilibria in the Ce–Ru–Ge system have been investigated by Shapiev (1993) by means of X-ray and metallographic analyses of 125 ternary alloys, which were arc

Fig. 48. Ce–Ru–Ge, isothermal section at 870 K.

melted and subsequently annealed in evacuated silica tubes at 870 K for 1000 hours and finally quenched in water. Starting materials were Ce 99.0 mass%, Ru 99.99 mass%, Ge 99.99 mass%. According to phase diagram, seven ternary compounds exist within the Ce–Ru–Ge system at 870 K (fig. 48). The mutual solid solubilities of binary compounds were found to be small, i.e. approximately 1–2 at.% of third component.

Early investigations of the  $\text{CeRu}_2\text{Ge}_2$  (1) compound determined it to have the  $\text{CeGa}_2\text{Al}_2$ -type structure:  $a = 0.4263$ ,  $c = 1.008$  after Felner and Nowik (1985) from X-ray powder analysis of induction melted alloy and  $a = 0.4270$ ,  $c = 1.0088$  (Francois et al. 1985) from X-ray powder analysis of alloy obtained by powder metallurgical reaction at 1273 K. Starting components were Ce (3N), Ru (4N) and Ge (4N). The crystal structure type was confirmed by Shapiev (1993) with lattice parameters  $a = 0.42717$ ,  $c = 1.0054$  from arc melted alloy annealed at 870 K.

Venturini et al. (1986b) and Shapiev (1993) reported the structure for the  $\text{Ce}_2\text{Ru}_3\text{Ge}_5$  compound (2) crystallizing with the  $\text{U}_2\text{Co}_3\text{Si}_5$ -type structure. Lattice parameters were reported to be  $a = 0.99197$ ,  $b = 1.238$ ,  $c = 0.5887$  (Venturini et al. 1986b; X-ray powder diffraction; for sample preparation, see  $\text{La}_2\text{Ru}_3\text{Ge}_5$ ) and  $a = 1.003$ ,  $b = 1.204$ ,  $c = 0.5895$  (Shapiev 1993).

The crystal structure of the  $\text{CeRuGe}$  compound (4) was investigated by Welter et al. (1993b). It was found to adopt the  $\text{PbFCl}$  type,  $a = 0.4275$ ,  $c = 0.6871$  (X-ray powder diffraction). The compound was prepared from commercially available high-purity elements. A compacted stoichiometric mixture pellet was heated to 1173 K under argon in a sealed silica tube for preliminary homogenization and then melted in an induction furnace. Shapiev (1993) reported the same crystal structure with slightly different lattice parameters:  $a = 0.4195$ ,  $c = 0.6916$ .

$\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type structure was announced for the  $\text{Ce}_3\text{Ru}_4\text{Ge}_{13}$  compound ( $a=0.9045$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. Starting materials were Ce (3N), Ru (3N), Ge (6N). Ghosh et al. (1995) reported on combined X-ray and neutron diffraction studies of the  $\text{Ce}_{4-x}\text{Ru}_4\text{Ge}_{12+x}$  alloys ( $a=0.90661$  for  $x=0$  and  $a=0.90494$  for  $x=1$ ). The samples were arc melted and annealed at 1170 K for two weeks. At variance with these data, Shapiev observed  $\text{CeRuGe}_3$  (3) with the  $\text{ScNiSi}_3$  type, lattice parameters  $a=2.185$ ,  $b=0.4234$ ,  $c=0.4285$ , from X-ray powder analysis of arc melted alloy annealed at 870 K.

Gladyshevsky et al. (1992) reported on the existence of the  $\text{Ce}_5\text{RuGe}_2$  (7) compound with a  $\text{S}_5\text{HFY}_2$ -anti-type structure,  $a=1.2255$ ,  $b=0.8898$ ,  $c=0.8008$  (X-ray single-crystal data). The single crystal was obtained from an alloy which was arc melted and annealed at 870 K.

Two compounds of unknown structure [ $\sim\text{Ce}_2\text{RuGe}$  (5) and  $\sim\text{Ce}_5\text{Ru}_2\text{Ge}$  (6)] were observed by Shapiev (1993) from arc melted samples annealed at 870 K.

$\text{Ce}_3\text{Ru}_2\text{Ge}_2$  was found to crystallize with  $\text{La}_3\text{Ni}_2\text{Ga}_2$ -type ( $a=0.5751$ ,  $b=0.7934$ ,  $c=1.3657$ , X-ray powder diffraction) from an arc melted and sample annealed at 870 K (Bodak et al. 1989b). This phase is not shown in the Ce–Ru–Ge phase diagram of fig. 48.

#### 4.4.8. Ce–Rh–Ge

The phase equilibria in the Ce–Rh–Ge system have been investigated by Shapiev (1993) by means of X-ray and metallographic analyses of 219 ternary alloys, which were arc melted and subsequently annealed in evacuated silica tubes for 1000 hours at 870 K and finally quenched in water. Starting materials were Ce 99.0 mass%, Rh 99.99 mass%, Ge 99.99 mass%. According to the phase diagram, twenty ternary compounds exist within the Ce–Rh–Ge system at 870 K (fig. 49). The limits of solid solutions originating at binary Ce–Rh and Rh–Ge compounds are not indicated by Shapiev (1993).

Venturini et al. (1985b) reported on an X-ray powder diffraction study of the  $\text{CeRhGe}_3$  compound (9) from a sample which was prepared by heating a mixture of starting components (Ce 3N, Rh 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to adopt the  $\text{BaNiSn}_3$ -type ( $a=0.4394$ ,  $c=1.0026$ ). Shapiev (1993) confirmed the crystal structure and reported the lattice parameters  $a=0.4394$ ,  $c=1.0019$ .

Early investigations on the  $\text{CeRh}_2\text{Ge}_2$  compound (7) determined the  $\text{CeGa}_2\text{Al}_2$ -type:  $a=0.4161$ ,  $c=1.045$  (Felner and Nowik (1985)) and  $a=0.4160$ ,  $c=1.0438$  (Francois et al. 1985). For sample preparation, see  $\text{CeRu}_2\text{Ge}_2$ . The crystal structure type was confirmed by Shapiev (1993):  $a=0.4154$ ,  $c=1.0472$  from X-ray powder diffraction of an alloy which was arc melted and annealed at 870 K.

$\text{Ce}_2\text{Rh}_3\text{Ge}_5$  (8) was found to crystallize with  $\text{U}_2\text{Co}_3\text{Si}_5$ -type ( $a=1.0097$ ,  $b=1.209$ ,  $c=0.5987$ ) by Venturini et al. (1986b) from X-ray powder analysis. Lattice parameters after Shapiev are  $a=0.9856$ ,  $b=1.2049$ ,  $c=0.5851$ .

Hovestreydt et al. (1982) reported the crystal structure of the  $\text{CeRhGe}$  compound (15) ( $\text{TiNiSi}$  type,  $a=0.7424$ ,  $b=0.4468$ ,  $c=0.7120$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. Starting components were Ce (3N), Rh (4N)

Fig. 49. Ce–Rh–Ge, isothermal section at 870 K.

and Ge (5N). Shapiev (1993) confirmed the TiNiSi-type for the sample annealed at 870 K ( $a=0.7199$ ,  $b=0.4352$ ,  $c=0.7378$ ; X-ray powder diffraction).

Gladyshevsky et al. (1991a) reported on the crystal structure of the  $\text{Ce}_3\text{Rh}_2\text{Ge}_2$  (18) compound ( $\text{La}_3\text{Ni}_2\text{Ge}_2$  type,  $a=0.57001$ ,  $b=0.8099$ ,  $c=1.3461$ ; X-ray single-crystal method). For the details of sample preparation, see  $\text{La}_3\text{Rh}_2\text{Ge}_2$ .

$\text{CeRh}_{1-x}\text{Ge}_{2+x}$  (13) with a new structure type was investigated by Shapiev et al. (1991):  $a=0.4322$ ,  $b=0.4329$ ,  $c=1.7107$  by a single-crystal method. For the experimental procedure, see Ce–Rh–Ge.

Verniere et al. (1995) mentioned the existence of  $\text{Ce}_4\text{Rh}_{13}\text{Ge}_9$  (4) with  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type. No lattice parameters were given. For experimental details and purity of starting metals see La–Ir–Ge. Salamakha and Sologub (1997) investigated the crystal structure and established the lattice parameters  $a=0.4055$ ,  $b=1.1372$ ,  $c=1.9804$  (X-ray powder data; arc melted sample annealed at 870 K).

Investigating the phase diagram, Shapiev (1993) established the crystal structure for  $\text{Ce}_3\text{Rh}_4\text{Ge}_{13}$  (5) ( $\text{Y}_3\text{Co}_4\text{Ge}_{13}$  type,  $a=0.908$ ), for  $\text{CeRh}_{1.4}\text{Ge}_{0.6}$  (14) ( $\text{MgZn}_2$  type,  $a=0.5310$ ,  $c=0.8950$ ) and for  $\text{CeRh}_{0.5}\text{Ge}_{1.5}$  (16) ( $\text{AlB}_2$  type,  $a=0.4220$ ,  $a=0.4208$ ), and observed ten compounds with unknown structures:  $\text{CeRh}_7\text{Ge}_6$  (1),  $\text{CeRh}_6\text{Ge}_2$  (2),  $\text{CeRh}_5\text{Ge}_3$  (3),  $\text{Ce}_3\text{Rh}_9\text{Ge}_5$  (6),  $\text{Ce}_2\text{Rh}_5\text{Ge}_2$  (10),  $\text{Ce}_2\text{Rh}_4\text{Ge}_3$  (11),  $\text{CeRh}_2\text{Ge}$  (12),  $\text{Ce}_2\text{RhGe}_2$  (17),  $\text{Ce}_2\text{RhGe}$  (19),  $\text{Ce}_7\text{RhGe}_2$  (20).

#### 4.4.9. Ce–Pd–Ge

A systematic study of the Ce–Pd–Ge system at 870 K was performed by Griбанov (1994) over the whole concentration region by means of X-ray powder and single-crystal analyses as well as using metallography and microprobe analyses. The samples were prepared

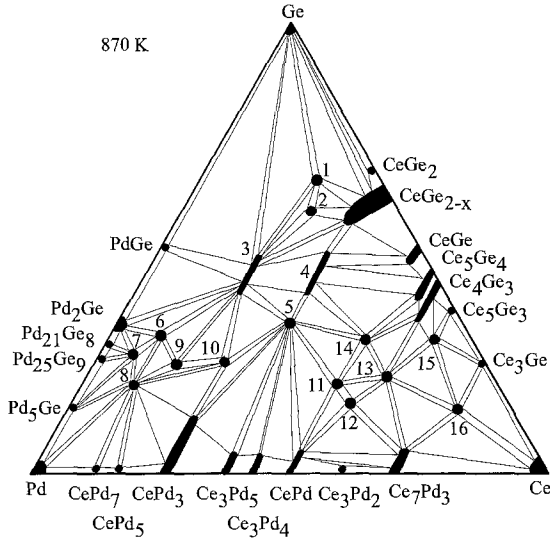

Fig. 50. Ce-Pd-Ge, isothermal section at 870 K.

by arc melting under argon the proper amount of starting elements, and annealed in evacuated quartz ampoules at 870 K for 720 hours. Starting materials were 99.8 mass% pure or better.

The phase-field distribution in the isothermal section at 870 K is characterized by existence of sixteen ternary compounds (fig. 50). Maximum solubility of germanium in the binary compounds of Ce-Pd and Ce-Ge systems is 12 at.% Ge for CePd<sub>3</sub>. CeGe<sub>2-x</sub> dissolves 11 at.% Pd. Solubility of cerium in the palladium germanides was found to be negligible. As reported by Griбанov (1994), homogeneity fields were observed for the compounds CePd<sub>2</sub>Ge<sub>2</sub> (3) and Ce(Pd,Ge)<sub>2</sub> (4).

The crystal structure of the compounds Ce<sub>3</sub>Pd<sub>20</sub>Ge<sub>6</sub> (8) (own structure type,  $a = 1.24453$ , Griбанov et al. 1994) and Ce<sub>7</sub>Pd<sub>4</sub>Ge<sub>2</sub> (12) (own structure type,  $a = 0.9315$ ,  $b = 1.2277$ ,  $c = 1.2698$ ,  $\beta = 114.31^\circ$ , Griбанov et al. 1993b) was investigated by the X-ray single-crystal analysis of specimens obtained from alloys annealed at 870 K.

The existence of the CePd<sub>2</sub>Ge<sub>2</sub> (3) compound (CeGa<sub>2</sub>Al<sub>2</sub> type,  $a = 0.4369$ ,  $c = 1.0055$ ) was reported by Rossi et al. (1979). For details of sample preparation see LaMn<sub>2</sub>Ge<sub>2</sub> under La-Mn-Ge. The existence of the 1:2:2 compound was confirmed by Griбанov (1994) (CeGa<sub>2</sub>Al<sub>2</sub> type,  $a = 0.4359$ ,  $b = 1.001$ ; X-ray powder diffraction) while investigating the Ce-Pd-Ge phase diagram at 870 K.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982) the compound CePdGe (5) adopts the KHg<sub>2</sub>-type structure. For sample preparation, see La-Pd-Ge. Starting materials were Ce (3N), Pd (4N) and Ge (5N). The existence of the CePdGe compound was later confirmed by Griбанov (1994) (KHg<sub>2</sub> type,  $a = 0.4480$ ,  $b = 0.7288$ ,  $c = 0.7672$ ; X-ray powder data).

The crystal structure of the compound CePd<sub>2</sub>Ge (10) was found to be of the YPd<sub>2</sub>Si type ( $a = 0.7668$ ,  $b = 0.6972$ ,  $c = 0.5757$ ; X-ray powder diffraction) by Jorda et al. (1983).

For the experimental procedure, see  $\text{LaPd}_2\text{Ge}$  under La–Pd–Ge. Starting materials were Pd 99.99 mass%, Ge specpure quality; Ce 99.9 mass%. Griбанov (1994) confirmed the structure type and determined the lattice parameters  $a=0.6980$ ,  $b=0.7702$ ,  $c=0.5789$  from X-ray powder analysis.

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Ce}_2\text{PdGe}_6$  (1) compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$  type,  $a=0.41784$ ,  $b=0.40900$ ,  $c=2.2043$ . For the experimental procedure, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge. The starting materials used were obtained from Johnson & Matthey, UK (99.9 mass%).

$\text{Ce}(\text{Pd},\text{Ge})_2$  (4) was found to crystallize with the  $\text{AlB}_2$  type,  $a=0.42946$ ,  $c=0.41732$  (Griбанov 1994; X-ray powder diffraction data).

The formation of nine more ternary phases with unknown structure has been observed by Griбанov et al. (1994) while investigating the isothermal section of the Ce–Pd–Ge system at 870 K:  $\sim\text{Ce}_{0.05}\text{Pd}_{0.68}\text{Ge}_{0.27}$  (7),  $\sim\text{Ce}_{0.10}\text{Pd}_{0.60}\text{Ge}_{0.30}$  (6),  $\sim\text{Ce}_{0.16}\text{Pd}_{0.60}\text{Ge}_{0.24}$  (9),  $\sim\text{Ce}_{0.25}\text{Pd}_{0.17}\text{Ge}_{0.58}$  (2),  $\sim\text{Ce}_{0.50}\text{Pd}_{0.30}\text{Ge}_{0.20}$  (11),  $\sim\text{Ce}_{0.50}\text{Pd}_{0.20}\text{Ge}_{0.30}$  (14),  $\sim\text{Ce}_{0.58}\text{Pd}_{0.20}\text{Ge}_{0.22}$  (13),  $\sim\text{Ce}_{0.62}\text{Pd}_{0.08}\text{Ge}_{0.30}$  (15) and  $\sim\text{Ce}_{0.75}\text{Pd}_{0.10}\text{Ge}_{0.15}$  (16).

#### 4.4.10. Ce–Ag–Ge

The phase equilibria in the Ce–Ag–Ge system were investigated by Protsyk (1994) by means of X-ray analysis of 80 alloys which were arc melted and subsequently annealed in evacuated silica tubes for 500 h at 770 K and finally quenched in water. Starting materials were Ce 99.85 mass%, Ag 99.9 mass% and Ge 99.99 mass%. The formation of ten new ternary silver germanides of cerium was observed (fig. 51). The  $\text{CeAg}_5$  compound was found to dissolve 10 at.% Ge. Crystal structure was established for four germanides; six ternary compounds were reported to be of unknown structure type. Crystallographic characteristics of ternary cerium silver germanides are listed in table 15.

Fig. 51. Ce–Ag–Ge, isothermal section at 770 K.

Table 15  
Crystallographic data for the ternary Ce–Ag–Ge compounds

No.	Compound	Structure	Lattice parameters (nm)			Reference
			<i>a</i>	<i>b</i>	<i>c</i>	
1	CeAg <sub>2</sub> Ge <sub>2</sub>	CeGa <sub>2</sub> Al <sub>2</sub>	0.4296		1.0955	Protsyk (1994)
3	Ce <sub>2</sub> AgGe <sub>6</sub>	Ce <sub>2</sub> CuGe <sub>6</sub>	0.43089	0.4144	2.1674	Sologub et al. (1995a)
5	CeAgGe	LiGaGe	0.45442		0.77108	Pecharsky et al. (1991)
6	CeAg <sub>0.8</sub> Ge <sub>1.2</sub>	AlB <sub>2</sub>	0.4375		0.4129	Protsyk (1994)
8	CeAg <sub>0.33</sub> Ge <sub>1.67</sub>	α-ThSi <sub>2</sub>	0.4239		1.4697	Protsyk (1994)

#### 4.4.11. Ce–Os–Ge

The only information on the interaction of components in the Ce–Os–Ge system is from Segre et al. (1981a) who announced a Pr<sub>3</sub>Rh<sub>4</sub>Sn<sub>13</sub>-type for the Ce<sub>3</sub>Os<sub>4</sub>Ge<sub>13</sub> compound ( $a=0.9075$ ) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. Starting materials were Ce (3N), Os (3N), Ge (6N).

#### 4.4.12. Ce–Ir–Ge

No ternary phase diagram has been established for the Ce–Ir–Ge system, however five ternary compounds have been observed and characterized by various groups of authors.

Ce<sub>2</sub>Ir<sub>3</sub>Ge<sub>5</sub> was found to crystallize with U<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub>-type ( $a=1.0189$ ,  $b=1.197$ ,  $c=0.6060$ ; X-ray powder diffraction method) by Venturini et al. (1985b).

Venturini et al. (1985b) reported on the X-ray powder diffraction study of the Ce<sub>3</sub>Ir<sub>4</sub>Ge<sub>13</sub> compound from a sample which was prepared by heating a mixture of starting components (Ce 3N, Ir 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to adopt the Yb<sub>3</sub>Rh<sub>4</sub>Sn<sub>13</sub> type,  $a=0.9061$ .

CeIr<sub>2</sub>Ge<sub>2</sub> is isotypic with the crystal structure of CaBe<sub>2</sub>Ge<sub>2</sub> with lattice parameters  $a=0.4246$ ,  $c=1.0098$  (Francois et al. 1985).

Verniere et al. (1995) observed the existence of the Ce<sub>4</sub>Ir<sub>13</sub>Ge<sub>9</sub> compound with a Ho<sub>4</sub>Ir<sub>13</sub>Ge<sub>9</sub> type from X-ray powder analysis and metallographic examination. No lattice parameters are available. For the experimental procedure, see La<sub>4</sub>Ir<sub>13</sub>Ge<sub>9</sub>.

Hovestreydt et al. (1982) reported the compound CeIrGe to adopt the TiNiSi type,  $a=0.7071$ ,  $b=0.4375$ ,  $c=0.7574$ , from X-ray powder diffraction. For sample preparation, see La–Pd–Ge.

#### 4.4.13. Ce–Pt–Ge

A systematic study of the Ce–Pt–Ge system at 870 K was performed by Gribanov et al. (1996) over the whole concentration region by means of X-ray powder and single-crystal analyses as well as using metallography and microprobe analyses. The samples were prepared by arc melting under argon and annealed in evacuated quartz ampoules at 870 K for 720 hours. Starting materials were 99.8 mass% pure or better. In the metallographic studies, Pt-rich samples (>50 at.% Pt) were etched in an HNO<sub>3</sub>+HCl (1:1) solution.

Fig. 52. Ce–Pt–Ge, isothermal section at 870 K.

A mixture of  $\text{HNO}_3 + \text{H}_2\text{O}$  (2:1) was used for etching alloys with <50 at.% Ce. Ce-rich samples (>50 at.% Ce) were etched by highly diluted  $\text{HNO}_3$ .

Phase relations are characterized by the existence of twelve ternary compounds and by the formation of extended solid solutions originating at Ce–Pt and Ce–Ge binary compounds (see fig. 52).  $\text{CePt}_5$  and  $\text{CePt}$  dissolve up to 20 at.% Ge. The maximum concentration of Ge in  $\text{Ce}_7(\text{Pt}, \text{Ge})_3$  was observed as 15 at.%. A large homogeneity range of not less than 24–33 at.% Ce was determined for the  $\text{CePt}_2$  compound; the limits of extension of  $\text{CePt}_2$  into the ternary system were not indicated by the author. The binary phases of the Pt–Ge system and the remaining binary phases in the other two systems dissolve less than 5 at.% of third component.

The crystal structures of the compounds  $\text{Ce}_3\text{Pt}_4\text{Ge}_6$  (4) (own structure type,  $a = 0.4419$ ,  $b = 0.4422$ ,  $c = 2.6222$ ; Griбанov et al. 1992a),  $\text{Ce}_2\text{Pt}_7\text{Ge}_4$  (10) (own structure type,  $a = 1.9866$ ,  $b = 0.4089$ ,  $c = 1.1439$ ; Griбанov et al. 1992b) and  $\text{Ce}_3\text{Pt}_{23}\text{Ge}_{11}$  (9) (own structure type,  $a = 1.71833$ ; Griбанov et al. 1993a) were investigated by X-ray single-crystal analysis of specimens obtained from alloys annealed at 870 K.  $\text{Ce}(\text{Pt}, \text{Ge})_2$  (5) was found to crystallize with the  $\text{AlB}_2$  type,  $a = 0.4272$ ,  $c = 0.4204$  (Griбанov et al. 1996; X-ray powder analysis).

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982) the compound  $\text{CePtGe}$  (7) adopted the  $\text{KHg}_2$ -type of structure,  $a = 0.4450$ ,  $b = 0.7347$ ,  $c = 0.7615$ . For sample preparation, see La–Pd–Ge. The crystal structure was confirmed later by Rogl et al. (1989),  $a = 0.44515$ ,  $b = 0.73439$ ,  $c = 0.76161$  (X-ray powder diffraction), and by Griбанov et al. (1996),  $a = 0.4445$ ,  $b = 0.7239$ ,  $c = 0.7609$  (X-ray powder diffraction).

The existence of the  $\text{CePt}_2\text{Ge}_2$  (3) compound ( $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.440$ ,  $c = 0.987$ ) was reported by Rossi et al. (1979). For sample preparation see  $\text{LaMn}_2\text{Ge}_2$  under La–Mn–Ge.

Dommann et al. (1985) observed the  $\text{CaBe}_2\text{Ge}_2$ -type for the  $\text{CePt}_2\text{Ge}_2$  compound with lattice parameters  $a=0.4397$ ,  $c=0.9802$  (X-ray single-crystal data) from an arc melted sample. Starting materials were Ce (3N), Ge (4N), Pt (3N).  $\text{CaBe}_2\text{Ge}_2$ -type was confirmed by Griбанov et al. (1996) for  $\text{CePt}_2\text{Ge}_2$ ;  $a=0.44033$ ,  $c=0.9808$  from an alloy annealed at 870 K (X-ray powder diffraction) and was shown to exist over a wide composition range, see fig. 52. Venturini et al. (1989a) investigated the crystal structure of  $\text{CePt}_2\text{Ge}_2$  from an arc melted sample annealed at 1273 K for 5 days. The crystal structure was found to belong to the  $\text{LaPt}_2\text{Ge}_2$  type,  $a=0.4389$ ,  $b=0.4402$ ,  $c=0.9818$ ,  $\beta=90.83^\circ$ . Starting materials were Ce (3N), Pt (4N) and Ge (4N).

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Ce}_2\text{PtGe}_6$  (1) compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$  type,  $a=0.41503$ ,  $b=0.40858$ ,  $c=2.2183$ . For sample preparation, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge. Griбанov et al. (1996) confirmed the structure type and obtained the lattice parameters  $a=0.4142$ ,  $b=0.4082$ ,  $c=2.209$  (X-ray powder diffraction).

Francois et al. (1987) reported the crystal structure of the  $\text{CePtGe}_2$  ( $\text{YIrGe}_2$  type,  $a=0.4428$ ,  $b=1.648$ ,  $c=0.8795$ ; X-ray powder data). The sample was prepared by heating the mixture of powders of starting components [Ce (3N), Ir (3N) and Ge (3N)] in an evacuated silica tube at 1173 K. The existence of the  $\text{CePtGe}_2$  compound was not confirmed by Griбанov et al. (1996) at 870 K.

The formation of five more ternary phases with unknown structure has been observed by Griбанov et al. (1996) while investigating the isothermal section of the Ce–Pt–Ge system at 870 K. They exist at the compositions  $\sim\text{Ce}_{11}\text{Pt}_{53}\text{Ge}_{36}$  (6),  $\sim\text{Ce}_{20}\text{Pt}_{60}\text{Ge}_{20}$  (11),  $\sim\text{Ce}_{25}\text{Pt}_{20}\text{Ge}_{55}$  (2),  $\sim\text{Ce}_{40}\text{Pt}_{28}\text{Ge}_{32}$  (8),  $\sim\text{Ce}_{62}\text{Pt}_{18}\text{Ge}_{20}$  (12).

#### 4.4.14. Ce–Au–Ge

Little information exists about the Ce–Au–Ge system; three ternary germanides were characterized.

A ternary compound of cerium with gold and germanium of the stoichiometric ratio 1:1:1 was identified and studied by means of X-ray and metallographic analyses by Rossi et al. (1992). The  $\text{CeAuGe}$  compound was found to have the  $\text{LiGaGe}$ -type structure with lattice parameters  $a=0.4464$ ,  $c=0.7910$ . The sample was prepared by melting the metals ( $\sim 99.9$  mass% for cerium and 99.99 mass% for gold and germanium) in an induction furnace and annealing at 1070 K for one week. The crystal structure of the  $\text{CeAuGe}$  compound has been confirmed by Pöttgen et al. (1996a) from an alloy which was prepared by melting a mixture of the elements in an arc furnace and subsequently annealing at 1070 K ( $a=0.44603$ ,  $c=0.79360$ ; X-ray powder data).

$\text{Ce}_2\text{AuGe}_6$  was reported to crystallize with a  $\text{Ce}_2\text{CuGe}_6$  type,  $a=0.42587$ ,  $b=0.41263$ ,  $c=2.1852$  (Sologub et al. 1995a; X-ray powder data). For sample preparation, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge.

The structure of  $\text{CeAu}_{0.75}\text{Ge}_{1.25}$  was derived by Jones et al. (1997) from single-crystal X-ray data:  $\text{AlB}_2$  structure type,  $a=0.4335$ ,  $c=0.4226$ . The sample was prepared from the elemental components by arc melting and subsequent annealing at 1170 K.

#### 4.5. Pr–d element–Ge systems

##### 4.5.1. Pr–Mn–Ge

No phase diagram exists for the system Pr–Mn–Ge, however, a series of ternary compounds have been observed and characterized.

The  $\text{PrMn}_2\text{Ge}_2$  compound have been prepared and studied by Rossi et al. (1978b). It was found to be of  $\text{CeGa}_2\text{Al}_2$  type with following lattice parameters  $a=0.4117$ ,  $c=1.0902$ . The alloy was obtain by melting under argon in an induction furnace. The samples were then annealed at 770 K for one week. Praseodymium used was of purity greater than 99.9 mass%, for manganese and germanium the purity was greater than 99.99 mass%.

A  $\text{PrMnGe}$  compound with  $\text{PbFCl}$ -type structure was observed by Welter et al. (1995);  $a=0.4182$ ,  $c=0.7308$ . The compound was prepared from commercially available high purity elements. A compacted pellet of stoichiometric mixture was sealed under argon (100 mmHg) in a silica tube, heated at 1273 K as a preliminary homogenization treatment and then melted in an induction furnace. The resulting ingot was annealed for 2 weeks at 1173 K.

##### 4.5.2. Pr–Fe–Ge

Phase equilibria for the complete isothermal section at 870 K have been determined by Fedyna (1988) using X-ray powder diffraction and microstructural analyses of 209 ternary alloys synthesized by arc melting ingots of Pr (99.75 mass%), Fe (99.90 mass%) and Ge (99.99 mass%). The alloys were annealed in evacuated quartz tubes for 500–900 hours at 870 K. The total number of compounds observed was nine. The mutual solid solubilities of the binary compounds were reported to be negligible. Phase equilibria in the isothermal section at 870 K are presented in fig. 53.

$\text{PrFe}_6\text{Ge}_6$  (1) was observed and studied by Mruz et al. (1984). It was found to crystallize with  $\text{YCo}_6\text{Ge}_6$  type, lattice parameters  $a=0.5091$ ,  $c=0.4036$ , by X-ray powder diffraction

Fig. 53. Pr–Fe–Ge, isothermal section at 870 K.

of arc melted alloy annealed at 870 K. The existence of the  $\text{PrFe}_6\text{Ge}_6$  compound was confirmed by Fedyna (1988) while constructing the isothermal section.

The formation and crystal structure of the  $\text{PrFe}_2\text{Ge}_2$  (2) compound was reported in an early investigation of praseodymium–iron–germanium combinations by Rossi et al. (1978a,b):  $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4055$ ,  $c=1.0540$  was later confirmed by Bara et al. (1990),  $a=0.4060$ ,  $c=1.0508$ . For sample preparation, see  $\text{LaMn}_2\text{Ge}_2$  under La–Mn–Ge, and  $\text{LaFe}_2\text{Ge}_2$  under La–Fe–Ge, respectively.

The crystal structures of four more compounds within Pr–Fe–Ge system at 870 K were determined by Fedyna (1988):  $\text{PrFeGe}_3$  (3) with  $\text{BaNiSn}_3$  type,  $a=0.4312$ ,  $c=0.9932$ ;  $\text{PrFe}_{1-x}\text{Ge}_2$ ,  $x=0.45$  (5) with  $\text{CeNiSi}_2$  type,  $a=0.4253$ ,  $b=1.6478$ ,  $c=0.4130$ ;  $\text{Pr}_4\text{Fe}_{1-x}\text{Ge}_7$ ,  $x=0.15$  (8) with  $\text{Sm}_4\text{CoGe}_7$  type,  $a=0.42166$ ,  $b=3.0520$ ,  $c=0.41278$ ;  $\text{Pr}_{117}\text{Fe}_{52}\text{Ge}_{112}$  (9) with  $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$  type,  $a=2.9428$ .

$\text{Pr}_6\text{Fe}_{13}\text{Ge}$  (7) was found to adopt the  $\text{Nd}_6\text{Fe}_{13}\text{Si}$  type by Weitzer et al. (1990),  $a=0.80986$ ,  $c=2.30836$ . For sample preparation, see  $\text{La}_6\text{Co}_{13}\text{Ge}$  under La–Co–Ge.

The crystal structures of two germanides  $\sim\text{Pr}_{2.3}\text{Fe}_{1.7}\text{Ge}_6$  (4) and  $\sim\text{Pr}_{2.7}\text{Fe}_{1.3}\text{Ge}_6$  (6) have not been solved yet.

#### 4.5.3. Pr–Co–Ge

Isothermal sections of the Pr–Co–Ge system at 1070 K (0–33 at.% Pr) and 670 K (33–100 at.% Pr) were derived by Fedyna (1988) employing X-ray phase and partly microstructural analyses of 287 alloys prepared by arc melting solid pieces of Pr (99.75 mass%), Co (99.90 mass%) and Ge (99.99 mass%). The melted buttons were then annealed in evacuated silica tubes for 500–900 hours. Thirteen ternary compounds were found to exist. The solubilities of cobalt in  $\text{PrGe}_{2-x}$  and  $\text{Pr}_5\text{Ge}_3$  binaries were established as 11 at.% and 8 at.%, respectively, from the variation of lattice parameters. Figure 54 represents the

Fig. 54. Pr–Co–Ge, isothermal sections at 1070 K (0–33 at.% Pr) and at 670 K (33–100 at.% Pr).

Table 16  
Crystallographic data for the ternary Pr–Co–Ge compounds

isothermal sections of the Pr–Co–Ge system at 1070 K and 670 K.

Crystallographic information on the Pr–Co–Ge ternary compounds is summarized in table 16.

The crystal structure of PrCoGe<sub>3</sub> (BaNiSn<sub>3</sub> type, *a* = 0.4307, *c* = 0.9803; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample prepared by heating a compacted mixture of starting materials (Pr in pieces, 99.9 mass%; Co and Ge in powder, 99.99 mass%) in an evacuated quartz tube at 1073 K. Later the same structure type was indicated by Fedyna (1988) for a sample with composition PrCo<sub>1-x</sub>Ge<sub>3</sub>, *x* = 0.136 (see table 16; X-ray powder diffraction data; for the experimental procedure, see above).

#### 4.5.4. Pr–Ni–Ge

The isothermal sections of the Pr–Ni–Ge phase diagram at 870 K (0–50 at.% Pr) and at 670 K (50–100 at.% Pr) was constructed by Fedyna (1988) from X-ray powder and microstructural analyses of 255 alloys. A detailed description of the experimental procedure is given under Pr–Fe–Ge. Starting materials were Pr (99.75 mass%), Ni (99.99 mass%) and Ge (99.99 mass%).

The phase relations are characterized by the existence of eleven ternary compounds and by the formation of an extended homogeneity region for the Pr(Ni,Ge)<sub>2-x</sub> (9) compound as well as two solid solutions originating at PrNi<sub>5</sub> (20 at.% Ge) and PrGe<sub>2-x</sub> (9 at.% Ni). The isothermal section of the Pr–Ni–Ge system after Fedyna (1988) is presented in fig. 55.

Bodak et al. (1982) investigated the crystal structure of the Pr<sub>3</sub>NiGe<sub>2</sub> compound (10) (Pr<sub>3</sub>NiGe<sub>2</sub> structure type, *a* = 1.1810, *b* = 0.4293, *c* = 1.1611) by the X-ray powder

Fig. 55. Pr–Ni–Ge, isothermal section at 870 K.

diffraction method. For sample preparation and purity of starting elements, see  $Y_3NiGe_2$  under Y–Ni–Ge.

Early investigations of the interaction of germanium with praseodymium and nickel has shown the existence of  $PrNi_{0.6}Ge_{1.4}$  with  $AlB_2$  type,  $a = 0.4161$ ,  $c = 0.4207$  (Gladyshevsky and Bodak 1965, Rieger and Parthé 1969a; X-ray powder diffraction). Fedyna (1988) confirmed the  $AlB_2$ -type for this composition and observed the formation of a large homogeneity field with the formula  $Pr(Ni_{0.42-0.28}Ge_{0.58-0.72})_{2-x}$ ,  $x = 0.14$  (9) and lattice parameters  $a = 0.4158-0.4150$ ,  $c = 0.4134-0.4220$ .

$PrNi_2Ge_2$  (2) is isotypic with  $CeGa_2Ge_2$ ;  $a = 0.4136$ ,  $c = 0.9844$  (Rieger and Parthé 1969b; X-ray powder diffraction).

The crystal structures of seven other compounds have been studied by Fedyna (1988).  $Pr_{1-x}(Ni,Ge)_{13}$ ,  $x = 0.24$  (1) belongs to the  $CeNi_{8.5}Si_{4.5}$ -type;  $Pr_2Ni_3Ge_5$  (3) crystallizes with the  $U_2Co_3Si_5$ -type structure,  $a = 0.9812$ ,  $b = 1.1832$ ,  $c = 0.5912$  (powder X-ray diffraction data);  $PrNiGe_3$  (4) is isostructural with the  $ScNiSi_3$  type,  $a = 2.1779$ ,  $b = 0.41052$ ,  $c = 0.41440$ ;  $Pr_2NiGe_6$  (5) was reported to crystallize with the  $Ce_2CuGe_6$  type,  $a = 0.40343$ ,  $b = 0.41124$ ,  $c = 2.1722$ ;  $Pr_3Ni_4Ge_4$  (6) was claimed to adopt the  $U_3Ni_4Ge_4$ -type structure,  $a = 0.4098$ ,  $b = 0.4182$ ,  $c = 2.4013$ ;  $PrNi_{1-x}Ge_2$ ,  $x = 0.33$  (7) is isotypic with  $CeNiSi_2$ ,  $a = 0.4210$ ,  $b = 1.668$ ,  $c = 0.4160$ ;  $PrNiGe$  (8) was found to be of  $TiNiSi$  type,  $a = 0.72757$ ,  $b = 0.43429$ ,  $c = 0.72981$ .

Investigating the isothermal section, Fedyna (1988) observed the  $\sim Pr_{0.5}Ni_{0.1}Ge_{0.4}$  (11) compound with unknown crystal.

#### 4.5.5. Pr–Cu–Ge

Praseodymium–copper–germanium combinations were investigated by various groups of authors, however no isothermal section was constructed for the Pr–Cu–Ge system so far.

Rieger and Parthé (1969a) investigated the occurrence of the  $AlB_2$ -type structure by means of X-ray powder diffraction of arc melted alloys. The data presented were  $PrCu_{1-0.67}Ge_{1-1.33}$  with  $a=0.4374-0.4183$ ,  $c=0.3971-0.4197$ . Iandelli (1993) confirmed the  $AlB_2$ -type ( $a=0.4288$ ,  $c=0.3942$ ; X-ray powder analysis) from the  $PrCuGe$  alloy which was prepared from mixed filings or powders of metals (praseodymium 99.7 mass%, copper and germanium 99.99 mass%) and sealed in tantalum crucibles under argon followed by melting in an induction furnace. Afterwards the sample was annealed for 10 days at 1023 K.

Sologub et al. (1995a) investigated the crystal structure of  $Pr_2CuGe_6$  alloy which was prepared by arc melting under argon and annealed at 1070 K in an evacuated quartz tube for 150 h. From X-ray powder analysis the compound was determined to have the  $Ce_2CuGe_6$ -type structure,  $a=0.41950$ ,  $b=0.40585$ ,  $c=2.1485$ .

$Pr_2Cu_3Ge_3$  was found to crystallize with the  $Ce_2Cu_3Ge_3$  structure type,  $a=0.4141$ ,  $c=1.7371$ ,  $c=0.4183$ , X-ray powder data (Konyk 1988). For sample preparation, see Ce–Cu–Ge.

Rieger and Parthé (1969b) synthesized  $PrCu_2Ge_2$  with the  $CeGa_2Al_2$ -type structure,  $a=0.4154$ ,  $c=1.0206$ .

The existence of a compound  $Pr_6Cu_8Ge_8$  with the  $Gd_6Cu_8Ge_8$  structure ( $a=1.421$ ,  $b=0.6687$ ,  $c=0.4293$ ) was reported by Fedyna et al. (1995) from X-ray powder diffraction data of arc melted alloy annealed at 870 K.

Francois et al. (1990) reported the crystal structure of the  $PrCu_{0.76}Ge_2$  compound ( $CeNiSi_2$  type,  $a=0.4247$ ,  $b=1.724$ ,  $c=0.4109$ ). For sample preparation, see LaFeGe<sub>2</sub> under La–Fe–Ge.

#### 4.5.6. Pr–Zn–Ge

No isothermal section is available for the ternary Pr–Zn–Ge system, however one ternary compound was observed and characterized by Rossi and Ferro (1996).  $PrZn_{1.5}Ge_{0.5}$  was found to crystallize with  $AlB_2$  type,  $a=0.4440$ ,  $c=0.3883$ , from X-ray powder diffraction of an alloy melted in an induction furnace and then annealed at 1070 K for one week. An electronic micrographic examination as well as microprobe microanalysis were carried out. The metals employed in sample synthesis had a nominal purity of 99.9 mass% for praseodymium, and 99.999 mass% for the other metals.

#### 4.5.7. Pr–Ru–Ge

The phase diagram for the Pr–Ru–Ge system is not available yet, however several groups of authors investigated praseodymium–ruthenium–germanium combinations with respect to the formation and crystal structure of the compounds.

Early investigations of the  $PrRu_2Ge_2$  compound determined the  $CeGa_2Al_2$ -type:  $a=0.4263$ ,  $c=1.0022$  (Francois et al. 1985) from X-ray powder analysis of alloy obtained by powder metallurgical reaction at 1273 K. Starting components were Pr (3N), Ru (4N) and Ge (4N).

Venturini et al. (1986b) reported that the  $Pr_2Ru_3Ge_5$  compound has the  $U_2Co_3Si_5$ -type structure. The lattice parameters were reported as  $a=0.9933$ ,  $b=1.247$ ,  $c=0.5846$  from X-ray powder diffraction.

$\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type was announced for the  $\text{Pr}_3\text{Ru}_4\text{Ge}_{13}$  compound ( $a=0.907$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. Starting materials were Pr (3N), Ru (3N), Ge (6N).

The crystal structure of the  $\text{PrRuGe}$  compound was investigated by Welter et al. (1993b). It was found to adopt the  $\text{PbFCl}$  type,  $a=4268$ ,  $c=0.6842$  (X-ray powder diffraction). The compound was prepared from commercially available high-purity elements. A compacted stoichiometric mixture in a silica tube sealed under argon was heated to 1173 K for preliminary homogenization and then melted in an induction furnace.

$\text{Pr}_3\text{Ru}_2\text{Ge}_2$  was found to crystallize with the  $\text{La}_3\text{Ni}_2\text{Ga}_2$  type ( $a=0.5699$ ,  $b=0.7909$ ,  $c=1.3593$ , X-ray powder diffraction) from an arc melted sample annealed at 870 K (Bodak et al. 1989a).

#### 4.5.8. *Pr–Rh–Ge*

Phase equilibria in the system  $\text{Pr–Rh–Ge}$  have not been established yet, but at least six different ternary phases have been verified.

$\text{Pr}_2\text{Rh}_3\text{Ge}_5$  was found to crystallize with  $\text{U}_2\text{Co}_3\text{Si}_5$ -type structure ( $a=1.0073$ ,  $b=1.209$ ,  $c=0.5969$ ) by Venturini et al. (1986b) from X-ray powder analysis.

Early investigations of the  $\text{PrRh}_2\text{Ge}_2$  compound determined it to have the  $\text{CeGa}_2\text{Al}_2$ -type structure:  $a=0.4147$ ,  $c=1.0436$  (Francois et al. 1985). For sample preparation, see  $\text{CeRu}_2\text{Ge}_2$  under  $\text{Ce–Ru–Ge}$ .

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{PrRhGe}_3$  compound from a sample prepared by heating of a mixture of the starting components (Pr 3N, Rh 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to adopt the  $\text{BaNiSn}_3$  type,  $a=0.4383$ ,  $c=1.0011$ .

Hovestreydt et al. (1982) reported the crystal structure of the  $\text{PrRhGe}$  compound ( $\text{TiNiSi}$  type,  $a=0.7376$ ,  $b=0.4476$ ,  $c=0.7124$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. Starting components were Pr (3N), Rh (4N) and Ge (5N).

Gladyshevsky et al. (1991a) reported on the crystal structure of  $\text{Pr}_3\text{Rh}_2\text{Ge}_2$  ( $\text{La}_3\text{Ni}_2\text{Ge}_2$  type,  $a=0.5674$ ,  $b=0.8059$ ,  $c=1.3445$ ; X-ray powder diffraction). For the details of sample preparation, see  $\text{La}_3\text{Rh}_2\text{Ge}_2$  under  $\text{La–Rh–Ge}$

$\text{Pr}_2\text{Rh}_3\text{Ge}$  crystallizes with the  $\text{Y}_2\text{Rh}_3\text{Ge}$ -type of structure with lattice parameters  $a=0.5626$ ,  $c=1.193$  (Cenzual et al. 1987).

Verniere et al. (1995) mentioned the existence of  $\text{Pr}_4\text{Rh}_{13}\text{Ge}_9$  compound with  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type; no lattice parameters were given. For the experimental details, see  $\text{La}_4\text{Rh}_{13}\text{Ge}_9$  under  $\text{La–Rh–Ge}$ .

#### 4.5.9. *Pr–Pd–Ge*

Phase relations have not been yet established for the  $\text{Pr–Pd–Ge}$  system; only three ternary compounds have been observed.

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Pr}_2\text{PdGe}_6$ , compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$  type structure,  $a=0.4152$ ,  $b=0.4073$ ,  $c=2.197$ . Samples were synthesized by argon arc melting followed by a heat

treatment at 870 K for 150 hours. Starting materials used were obtained from Johnson & Matthey, UK (99.9 mass%).

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound PrPdGe adopts the  $\text{KHg}_2$ -type structure,  $a=0.4472$ ,  $b=0.7256$ ,  $c=0.7654$ . The alloy was arc melted under argon and annealed at 1270 K for 1–2 weeks. The starting materials were Pr (3N), Pd (4N) and Ge (5N).

The crystal structure of the compound  $\text{PrPd}_2\text{Ge}$  was found to be of the  $\text{YPd}_2\text{Si}$  type ( $a=0.7617$ ,  $b=0.6993$ ,  $c=0.5735$ ; X-ray powder diffraction) by Jorda et al. (1983). The sample was obtained by induction melting under an argon atmosphere and annealing in evacuated quartz tube for 10 days at 1173 K. The starting materials were palladium (4N), germanium (4N), praseodymium (3N).

#### 4.5.10. Pr–Ag–Ge

Information on interaction of praseodymium with silver and germanium is due to the work of several groups of authors; six ternary compounds have been observed and analyzed. Crystallographic characteristics of the ternary Pr–Ag–Ge phases are listed in table 17.

Table 17  
Crystallographic data for the ternary Pr–Ag–Ge compounds

Compound	Structure	Lattice parameters (nm)			Reference
		<i>a</i>	<i>b</i>	<i>c</i>	
$\text{Pr}_2\text{AgGe}_6$	$\text{Ce}_2\text{CuGe}_6$	0.42887	0.41295	2.1610	Sologub et al. (1995a)
		0.42856	0.41263	2.15869	Savysyuk and Gladyshevsky (1995)
$\text{PrAg}_{0.8}\text{Ge}_{1.2}$	$\text{AlB}_2$	0.4356		0.4130	Protsyk (1994)
		0.43793		0.40903	Savysyuk and Gladyshevsky (1995)
$\text{PrAg}_2\text{Ge}_2$	$\text{CeGa}_2\text{Al}_2$	0.42801		1.09977	Savysyuk and Gladyshevsky (1995)
$\text{Pr}_3\text{Ag}_4\text{Ge}_4$	$\text{Gd}_3\text{Cu}_4\text{Ge}_4$	0.4342	0.71126	1.47306	Savysyuk and Gladyshevsky (1995)
$\text{PrAg}_{1.4}\text{Ge}_{0.6}$	$\text{Fe}_2\text{P}$	0.72989		0.43340	Savysyuk and Gladyshevsky (1995)
$\text{PrAgGe}$	$\text{LiGaGe}$	0.45276		0.76357	Savysyuk and Gladyshevsky (1995)

Savysyuk and Gladyshevsky (1995) employed X-ray powder diffraction analysis of arc melted samples, which were homogenized by annealing at 773 K and 1073 K for 1000 hours. For detailed experimental procedure for  $\text{Pr}_2\text{AgGe}_6$  (Sologub et al. 1995a) and  $\text{PrAg}_{0.8}\text{Ge}_{1.2}$  (Protsyk 1994), see  $\text{La}_2\text{AgGe}_6$  (under La–Ag–Ge) and Ce–Ag–Ge, respectively.

#### 4.5.11. Pr–Os–Ge

No phase diagram exists at present for the system Pr–Os–Ge, however, one ternary germanide has been observed and characterized by Segre et al. (1981a).  $\text{Pr}_3\text{Os}_4\text{Ge}_{13}$  was found to crystallize with the  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type structure,  $a=0.9098$ . For sample preparation, see  $\text{Ce}_3\text{Ru}_4\text{Ge}_{13}$  under Ce–Ru–Ge.

#### 4.5.12. Pr–Ir–Ge

Phase relations have not yet been established for the Pr–Ir–Ge system; information concerning the formation of six compounds and their crystal structure is due to the work of different groups of authors.

Francois et al. (1987) reported the crystal structure of the PrIrGe<sub>2</sub> (YIrGe<sub>2</sub> type,  $a=0.4393$ ,  $b=1.617$ ,  $c=0.8908$ ). The sample was prepared by heating the mixture of powders of starting components (Pr 3N, Ir 3N and Ge 3N) in evacuated silica tube at 1173 K.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound PrIrGe adopts the TiNiSi-type structure,  $a=0.7357$ ,  $b=0.4440$ ,  $c=0.71197$ . For the experimental procedure, see La–Ir–Ge.

PrIr<sub>2</sub>Ge<sub>2</sub> is isotypic with the crystal structure of CaBe<sub>2</sub>Ge<sub>2</sub> with lattice parameters  $a=0.4235$ ,  $c=1.0057$  (Francois et al. 1985).

Pr<sub>2</sub>Ir<sub>3</sub>Ge<sub>5</sub> was found to crystallize with the U<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub> type ( $a=1.0185$ ,  $b=1.190$ ,  $c=0.6045$ ) by Venturini et al. (1986b) from X-ray powder analysis.

Verniere et al. (1995) observed the existence Pr<sub>4</sub>Ir<sub>13</sub>Ge<sub>9</sub> compound with Ho<sub>4</sub>Ir<sub>13</sub>Ge<sub>9</sub>-type. Lattice parameters have not been established. For the experimental procedure, see La<sub>4</sub>Ir<sub>13</sub>Ge<sub>9</sub> under La–Ir–Ge.

Venturini et al. (1985b) reported on the X-ray powder diffraction study of the Pr<sub>3</sub>Ir<sub>4</sub>Ge<sub>13</sub> compound from a sample which was prepared by heating a mixture of starting components (Pr 3N, Ir 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to adopt the Yb<sub>3</sub>Rh<sub>4</sub>Sn<sub>13</sub>-type structure,  $a=0.9053$ .

#### 4.5.13. Pr–Pt–Ge

Francois et al. (1987) reported the crystal structure of the PrPtGe<sub>2</sub> (YIrGe<sub>2</sub> type,  $a=0.4416$ ,  $b=1.644$ ,  $c=0.8793$ ). For sample preparation, see PrIrGe<sub>2</sub> under Pr–Ir–Ge.

Venturini et al. (1989a) investigated the crystal structure of PrPt<sub>2</sub>Ge<sub>2</sub> from an arc melted sample annealed at 1273 K for 5 days. The crystal structure was found to belong to the LaPt<sub>2</sub>Ge<sub>2</sub> type,  $a=0.4374$ ,  $b=0.4396$ ,  $c=0.9779$ ,  $\beta=91.94^\circ$ . The starting materials were Pr (3N), Pt (4N) and Ge (4N).

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound PrPtGe adopts the KHg<sub>2</sub>-type of structure,  $a=0.4438$ ,  $b=0.7292$ ,  $c=0.7616$ . For the experimental procedure, see La–Ir–Ge.

Sologub et al. (1995a) reported on the X-ray powder analysis of the Pr<sub>2</sub>PtGe<sub>6</sub> compound which was found to crystallize with the Ce<sub>2</sub>CuGe<sub>6</sub> type structure,  $a=0.4134$ ,  $b=0.4070$ ,  $c=2.2084$ . For sample preparation, see La<sub>2</sub>PdGe<sub>6</sub> under La–Pd–Ge.

#### 4.5.14. Pr–Au–Ge

No ternary phase diagram exists for the Pr–Au–Ge system, however, a ternary compound of praseodymium with gold and germanium in the stoichiometric ratio 1:1:1 has been identified and studied by means of X-ray powder diffractometry and metallography by Rossi et al. (1992). The PrAuGe compound was found to adopt the LiGaGe type

with lattice parameters  $a=0.4457$ ,  $c=0.7803$ . The sample was prepared by melting the metals (99.9 mass% for praseodymium and 99.99 mass% for gold and germanium) in an induction furnace and annealing at 1070 K for one week.

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Pr}_2\text{AuGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$  type,  $a=0.4241$ ,  $b=0.4113$ ,  $c=2.1172$ . For sample preparation, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge.

#### 4.6. Nd–d element–Ge systems

##### 4.6.1. Nd–V–Ge

The phase equilibria in the Nd–V–Ge system have been investigated by Salamakha et al. (1994) by means of X-ray analysis of 40 ternary alloys. No ternary compounds were observed. The isothermal section of the phase diagram at 870 K is shown in fig. 56.

Fig. 56. Nd–V–Ge, isothermal section at 870 K.

The ternary samples used to derive the phase relations in the ternary section at 870 K, each with a total weight of 2 g, were synthesized by arc melting proper amounts of the constituent elements under high-purity argon on a water-cooled copper hearth. The starting materials were used in the form of ingots of high-purity elements: neodymium (99.85 mass%), vanadium (99.99 mass%), germanium (99.99 mass%). The weight losses were generally less than 1%. The alloys were annealed at 870 K in evacuated quartz tubes for 2 weeks and quenched in ice cold water.

##### 4.6.2. Nd–Cr–Ge

The isothermal section of the Nd–Cr–Ge phase diagram at 870 K was constructed by Salamakha et al. (1994). The phase relations are characterized by the formation of two

Fig. 57. Nd–Cr–Ge, isothermal section at 870 K. The curved line indicates the liquid immiscibility gap region.

ternary compounds,  $\text{Nd}_2\text{Cr}_9\text{Ge}_8$  (1) and  $\text{Nd}_{117}\text{Cr}_{52}\text{Ge}_{112}$  (2), and by a region of liquid immiscibility that stretches up to 20 at.% Ge (fig. 57). For details of sample preparation, see Nd–V–Ge. The purity of the starting materials was Nd 99.85 mass%, Cr 99.93 mass%, Ge mass 99.99%.

$\text{Nd}_2\text{Cr}_9\text{Ge}_8$  (own structure type,  $a=0.9388$ ,  $b=0.4046$ ,  $c=0.8045$ ) was observed by Bodak et al. (1989a) from X-ray single-crystal analysis. For sample preparation, see Nd–V–Ge.

Salamakha et al. (1994) observed the  $\text{Nd}_{117}\text{Cr}_{52}\text{Ge}_{112}$  compound in the course of investigating the Nd–Cr–Ge isothermal section. It was found to crystallize with the  $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$ -type structure,  $a=2.9439$  from X-ray powder analysis.

#### 4.6.3. Nd–Mn–Ge

The phase-field distribution in the Nd–Mn–Ge system at 870 K is characterized by the formation of three ternary compounds:  $\text{NdMn}_6\text{Ge}_6$  (1),  $\text{NdMn}_2\text{Ge}_2$  (2) and  $\text{NdMn}_x\text{Ge}_2$  (3) after Salamakha et al. (1994) (fig. 58). The samples were prepared by argon arc melting. Weight losses due to vaporization while melting were compensated beforehand by extra amounts of manganese (about 0.5 mass%). The arc melted buttons were annealed at 870 K for 2 weeks in vacuum-sealed quartz capsules and finally quenched by submerging the ampoules into cold water. The starting materials were Nd 99.85 mass%, Mn 99.98 mass%, Ge 99.99 mass%.

$\text{NdMn}_6\text{Ge}_6$ (1) has been found by Salamakha et al. (1994) from X-ray powder diffraction to be isostructural with the  $\text{YCo}_6\text{Ge}_6$  type,  $a=0.5249$ ,  $c=0.4098$ . For the experimental procedure, see above.

$\text{NdMn}_2\text{Ge}_2$  (2) was reported to crystallize with the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4105$ ,  $c=1.0216$  (Salamakha et al. 1994; X-ray powder diffraction).

Fig. 58. Nd–Mn–Ge, isothermal section at 870 K.

The crystallographic characteristics for  $\text{NdMn}_x\text{Ge}_2$  (3) were reported by Salamakha et al. 1994 from X-ray powder analysis (CeNiSi<sub>2</sub> type,  $a = 0.4232$ ,  $b = 1.653$ ,  $c = 0.4092$ ).

A compound of equiatomic composition with the PbFCI type was observed by Welter et al. (1995) at 1070 K with lattice parameters  $a = 0.4134$ ,  $c = 0.7375$ . For sample preparation, see Pr–Mn–Ge. Apparently the NdMnGe phase does not exist at 870 K (fig. 58).

#### 4.6.4. Nd–Fe–Ge

Figure 59 represents the isothermal section of the Nd–Fe–Ge system at 870 K as derived

Fig. 59. Nd–Fe–Ge, isothermal section at 870 K.

Table 18  
Crystallographic data for the ternary Nd–Fe–Ge compounds at 870 K

No.	Compound	Structure	Lattice parameters (nm)			Reference
			<i>a</i>	<i>b</i>	<i>c</i>	
1	NdFe <sub>6</sub> Ge <sub>6</sub>	YCo <sub>6</sub> Ge <sub>6</sub>	0.5142		0.4049	Salamakha et al. (1996b)
2	NdFe <sub>2</sub> Ge <sub>2</sub>	CeGa <sub>2</sub> Al <sub>2</sub>	0.4038		1.0510	Salamakha et al. (1996b)
3	~Nd <sub>3</sub> Fe <sub>3</sub> Ge <sub>12</sub>	unknown				Salamakha et al. (1996b)
4	~Nd <sub>3</sub> Fe <sub>2</sub> Ge <sub>13</sub>	unknown				Salamakha et al. (1996b)
5	NdFe <sub>0.37</sub> Ge <sub>2</sub>	CeNiSi <sub>2</sub>	0.4214	1.6450	0.4084	Salamakha et al. (1996b)
6	~Nd <sub>3</sub> FeGe <sub>7</sub>	unknown				Salamakha et al. (1996b)
7	~Nd <sub>4</sub> FeGe <sub>10</sub>	orthorhomb	0.422	0.403	2.828	Salamakha et al. (1996b)
8	Nd <sub>4</sub> Fe <sub>0.64</sub> Ge <sub>7</sub>	Sm <sub>4</sub> Co <sub>1-x</sub> Ge <sub>7</sub>	0.4198	0.4095	3.037	Salamakha et al. (1996b)

from X-ray phase analysis of 150 samples by Salamakha et al. (1996b). The phase-field distribution is characterized by the presence of eight ternary compounds. The binary compound Fe<sub>3</sub>Ge does not appear in the Nd–Fe–Ge ternary. None of the binary phases shows an appreciable range of mutual solid solubility. For the experimental details, see Nd–V–Ge. The starting materials were Nd 99.85 mass%, Fe 99.98 mass%, Ge 99.99 mass%.

Crystallographic data of the ternary phases, observed by Salamakha et al. (1996b) investigating the isothermal section of the Nd–Fe–Ge system, are listed in table 18.

Two more ternary compounds are known from early investigations of ternary neodymium–iron–germanium combinations performed by Felner and Schieber (1973) and Weitzer et al. (1990) which have not been observed in the course of studying the Nd–Fe–Ge isothermal section at 870 K. The NdFe<sub>0.67</sub>Ge<sub>1.33</sub> compound was found to adopt the AlB<sub>2</sub> type (*a* = 0.4174, *c* = 0.4163; X-ray powder diffraction) (Felner and Schieber 1973). The samples were prepared by melting elements together (Nd 99.9 mass%, Ge 99.99 mass%, Fe 99.95 mass%). The metals were mixed and heated in an alumina crucible in an induction furnace at about 1870 K under a protective argon atmosphere. The samples were homogenized by annealing them in the induction furnace at the melting temperature for about 30 min. The crystal structure of the Nd<sub>6</sub>Fe<sub>13</sub>Ge compound was reported by Weitzer et al. (1990) (Nd<sub>6</sub>Fe<sub>13</sub>Si type, *a* = 0.8043, *c* = 2.3204). The sample was melted under argon and annealed at 1073 K for 5 days. The starting materials were commercially available high-purity elements.

#### 4.6.5. Nd–Co–Ge

The isothermal section of the Nd–Co–Ge system at 870 K is shown in fig. 60. The phase-field distribution is characterized by the presence of sixteen ternary compounds as reported by Salamakha (1997). Mutual solid solubilities of the binary compounds are insignificantly small. For sample preparation, see Nd–V–Ge. The starting materials were Nd 99.85 mass%, Co 99.99 mass%, Ge 99.99 mass% pure.

Crystallographic data of the ternary Nd–Co–Ge compounds are listed in table 19.

Fig. 60. Nd–Co–Ge, isothermal section at 870 K.

Table 19

				$\beta = 118.60^\circ$		
11	Nd <sub>117</sub> Co <sub>52</sub> Ge <sub>112</sub>	Tb <sub>117</sub> Fe <sub>52</sub> Ge <sub>112</sub>	2.9162			Salamakha (1997)
12	Nd <sub>6</sub> Co <sub>5</sub> Ge <sub>2.2</sub>	own	0.9272		0.4188	Salamakha et al. (1986)
13	Nd <sub>3</sub> CoGe <sub>2</sub>	La <sub>3</sub> NiGe <sub>2</sub>	1.207	0.403	1.157	Salamakha (1997)
14	~Nd <sub>11</sub> Co <sub>4</sub> Ge <sub>5</sub>	unknown				Salamakha (1997)
15	~Nd <sub>5</sub> CoGe <sub>2</sub>	unknown				Salamakha (1997)
16	~Nd <sub>5</sub> Co <sub>2</sub> Ge	unknown				Salamakha (1997)

Venturini et al. (1986b), from X-ray powder diffraction analysis of a sample synthesized by powder metallurgical reaction at 1173 K, characterized the compound  $\text{Nd}_2\text{Co}_3\text{Ge}_5$  to be isostructural with the  $\text{Lu}_2\text{Co}_3\text{Si}_5$ -type ( $a = 1.115$ ,  $b = 1.193$ ,  $c = 0.5812$ ,  $\gamma = 118.45^\circ$ ). These data suggest that  $\text{Nd}_2\text{Co}_3\text{Ge}_5$  has two polymorphic phases (compound 2, table 19).

#### 4.6.6. Nd–Ni–Ge

Figure 61 shows the isothermal section of the Nd–Ni–Ge system at 870 K as derived from X-ray phase analysis of 180 arc melted samples which were annealed and subsequently quenched in water (Salamakha et al. 1996c). Starting materials were Nd 99.85 mass%, Ni 99.99 mass%, Ge 99.99 mass%. The phase-field distribution is characterized by the presence of nine ternary compounds. The binary compounds  $\text{Nd}_2\text{Ni}_{17}$  and  $\text{NdNi}_5$  dissolve approximately 15 at.% Ge.

Fig. 61. Nd–Ni–Ge, isothermal section at 870 K.

Crystallographic data for the ternary phases of the Nd–Ni–Ge system are listed in table 20.

Additionally two ternary compounds of an unknown structure type,  $\sim\text{Nd}_5\text{NiGe}_2$  and  $\sim\text{Nd}_5\text{Ni}_2\text{Ge}$ , have been observed by Salamakha et al. (1996c) in “as-cast” samples (X-ray powder analysis).

#### 4.6.7. Nd–Cu–Ge

Information about the phase equilibria in the Nd–Cu–Ge system (fig. 62) is due to the work of Salamakha (1988) who employed X-ray phase analysis of argon arc melted ternary alloys; the samples were annealed in vacuum-sealed quartz ampoules at 870 K for

Table 20

Fig. 62. Nd–Cu–Ge, isothermal section at 870 K.

300 hours. The formation of six ternary phases has been reported. Mutual solid solubilities of the binaries were reported to be negligible.

The crystallographic characteristics of the ternary compounds of the Nd–Cu–Ge system at 870 K are listed in table 21.

One more compound has been observed and investigated by Salamakha et al. (1996d) from an as-cast sample: Nd<sub>6</sub>Cu<sub>8</sub>Ge<sub>8</sub> (Gd<sub>6</sub>Cu<sub>8</sub>Ge<sub>8</sub> type,  $a=0.4302$ ,  $b=0.6711$ ,  $c=1.4249$ ; X-ray single-crystal method).

#### 4.6.8. Nd–Zn–Ge

No isothermal section is available for the ternary Nd–Zn–Ge system, however one ternary compound was observed and characterized by Rossi and Ferro (1996). NdZn<sub>1.5</sub>Ge<sub>0.5</sub> was found to crystallize with the AlB<sub>2</sub> type,  $a = 0.4432$ ,  $c = 0.3820$ , from X-ray powder diffraction of an induction-melted alloy which was annealed at 1070 K for one week. Electronic micrographic examination as well as microprobe microanalysis was carried out. The metals employed in sample synthesis had a nominal purity of 99.9 mass% for neodymium, and 99.999 mass% for the other metals.

#### 4.6.9. Nd–Zr–Ge

Salamakha and Starodub (1991) were the first to investigate the phase relations within the isothermal section at 870 K over the whole concentration region by X-ray powder analysis (fig. 63). No ternary compounds were observed. For sample preparation, see Nd–V–Ge.

Fig. 63. Nd–Zr–Ge, isothermal section at 870 K.

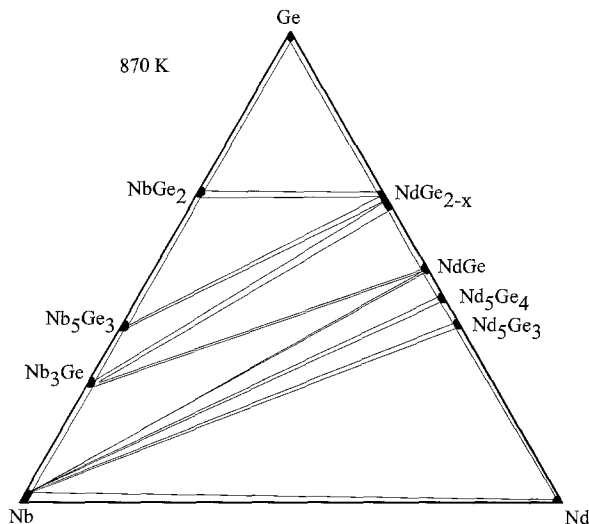

Fig. 64. Nd–Nb–Ge, isothermal section at 870 K.

#### 4.6.10. Nd–Nb–Ge

The phase relations in the ternary system Nd–Nb–Ge at 870 K are presented in fig. 64 after Salamakha (1997). As determined from X-ray powder diffraction analysis of samples annealed at 870 K, phase equilibria revealed the absence of ternary compounds. For sample preparation, see Nd–V–Ge.

#### 4.6.11. Nd–Mo–Ge

Salamakha (1997) reported the Nd–Mo–Ge phase diagram shown in fig. 65. No ternary compounds or solid solutions have been observed at 870 K. For sample preparation, see Nd–V–Ge.

Fig. 65. Nd–Mo–Ge, isothermal section at 870 K.

## 4.6.12. Nd–Ru–Ge

Phase equilibria in the Nd–Ru–Ge system have been derived by Salamakha et al. (1996e) by means of powder X-ray analysis of samples prepared by direct arc melting of high-purity components (Nd 99.85 mass%, Ru 99.9 mass%, Ge 99.99 mass%), annealed at 870 K for two weeks in evacuated quartz ampoules and quenched in cold water. The isothermal section is shown in fig. 66. The phase relations are characterized by the existence of seven ternary neodymium–ruthenium germanides. Mutual solid solubilities of the binary compounds were observed to be negligible.

Crystallographic data of ternary Nd–Ru–Ge compounds are listed in table 22.

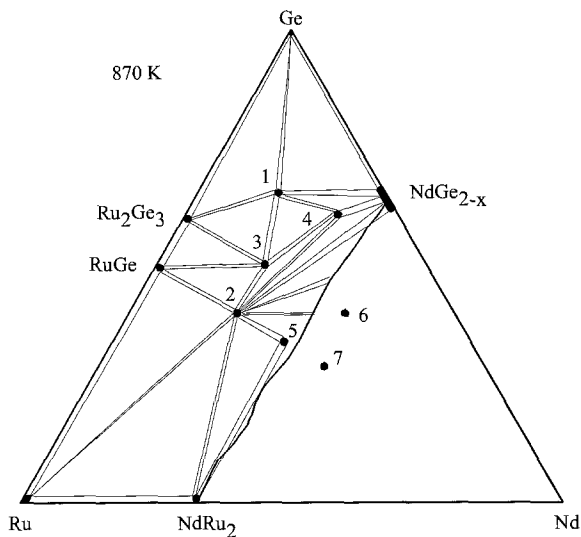

Fig. 66. Nd–Ru–Ge, partial isothermal section at 870 K. (0–33 at.% Nd).

#### 4.6.13. Nd–Rh(Pd)–Ge

No ternary phase diagrams have been established for the Nd–Rh–Ge system and the Nd–Pd–Ge system, but the crystal structures of ternary compounds have been characterized by several groups of authors. Crystallographic data for the ternary neodymium–rhodium germanides and neodymium–palladium germanides are compiled in table 23.

#### 4.6.14. Nd–Ag–Ge

Phase equilibria have been established in the ternary Nd–Ag–Ge system over the whole concentration region for the isothermal sections at 870 K and 1070 K by Salamakha et al. (1996f) and Zaplatynsky et al. (1996) (figs. 67a,b). The existence of four and five ternary compounds respectively have been observed. Samples were melted from pieces of high purity components (Nd 99.85 mass%, Ag 99.99 mass%, Ge 99.99 mass%) under argon atmosphere in an arc furnace with water-cooled copper hearth. The ingots were subsequently annealed at 870 K (1070 K) and quenched in cold water. The isothermal sections were constructed using X-ray powder diffraction film data obtained by the Debye–Scherrer technique with non-filtered CrK radiation.

Crystallographic characteristics of the ternary phases which exist within the Nd–Ag–Ge system at 870 K and 1070 K are listed in table 24.

Fig. 67. Nd–Ag–Ge, isothermal sections at 870 K (a) and 1070 K (b).

#### 4.6.15. Nd–Hf–Ge

Salamakha and Starodub (1991) reported the phase diagram shown in fig. 68. No ternary compounds or solid solutions have been observed at 870 K. For sample preparation, see Nd–V–Ge.

#### 4.6.16. Nd–Ta–Ge

The results of X-ray investigations of the isothermal section of the Nd–Ta–Ge systems at 870 K are shown in fig. 69 after Salamakha (1997). No ternary compounds were observed. For sample preparation, see Nd–V–Ge.

#### 4.6.17. Nd–W–Ge

Salamakha (1997) derived the Nd–W–Ge phase diagram shown in fig. 70. No solid solubility or ternary compounds have been found at 870 K. For sample preparation, see Nd–V–Ge.

Fig. 68. Nd–Hf–Ge, isothermal section at 870 K.

Fig. 69. Nd–Ta–Ge, isothermal section at 870 K.

#### 4.6.18. Nd–Re–Ge

No ternary compounds were found in the ternary Nd–Re–Ge system at 870 K (fig. 71) (Salamakha 1997). For sample preparation, see Nd–V–Ge.

#### 4.6.19. Nd–Os–Ge

The partial isothermal section of the Nd–Os–Ge system at 870 K is shown in fig. 72, after Salamakha et al. (1996e). Samples were prepared in the same manner as for the

Fig. 70. Nd-W-Ge, isothermal section at 870 K.

Fig. 71. Nd-Re-Ge, isothermal section at 870 K.

investigation of the Nd-Ru-Ge system. Two ternary compounds were found to exist within the concentration region under investigation.

The  $\text{Nd}_3\text{Os}_4\text{Ge}_{13}$  (1) compound has been found to crystallize with  $\text{Y}_3\text{Co}_4\text{Ge}_{13}$  type at 870 K,  $a = 0.9080$  nm (Salamakha et al. 1989a) whereas at 1170 K the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type has been realized (Segre et al. 1981b).

The crystal structure of the  $\sim\text{Nd}_3\text{OsGe}_6$  (2) compound has not been determined.

The  $\text{Nd}_2\text{Os}_3\text{Ge}_5$  compound was established to crystallize with the  $\text{U}_2\text{Co}_3\text{Si}_5$ -type structure from X-ray powder diffraction of an as-cast specimen (Salamakha et al. 1996e).

Fig. 72. Nd-Os-Ge, partial isothermal section at 870 K (0-33 at.% Nd).

#### 4.6.20. Nd-Ir(Pt)-Ge

No ternary phase diagrams have been established for the Nd-Ir(Pt)-Ge systems, but the crystal structures of ternary compounds have been characterized by various authors (see table 25).

#### 4.6.21. Nd–Au–Ge

A partial isothermal section of the Nd–Au–Ge system at 870 K is shown in fig. 73, after Salamakha (1997). The phase relations are characterized by the formation of five ternary neodymium germanides of gold. Their crystallographic data are listed in table 26. For the details of sample preparation, see Nd–Ag–Ge.

#### 4.7. Sm–d element–Ge systems

##### 4.7.1. Sm–Mn–Ge

No phase diagram is available for the system Sm–Mn–Ge, however, a series of ternary compounds have been observed and characterized.

The  $\text{SmMn}_2\text{Ge}_2$  compound has been prepared and studied by Rossi et al. (1978b). It was found to be of  $\text{CeGa}_2\text{Al}_2$  type with lattice parameters  $a=0.4062$ ,  $c=1.0896$ . For sample preparation, see  $\text{LaMn}_2\text{Ge}_2$  under La–Mn–Ge.

$\text{SmMnGe}$  with PbFCl-type was observed by Welter et al. (1995),  $a=0.4134$ ,  $c=0.7375$ . The compound was prepared from commercially available high-purity elements. A compacted pellet of stoichiometric mixture was sealed under argon (100 mmHg) in a silica tube, heated at 1273 K as a preliminary homogenization treatment and then melted in an induction furnace. The resulting ingot was annealed for 2 weeks at 1173 K.

$\text{SmMn}_6\text{Ge}_6$  was found to crystallize in the  $\text{YCo}_6\text{Ge}_6$ -type structure by Venturini et al. (1992),  $a=0.5245$ ,  $c=0.8187$  (X-ray powder diffraction data). The alloy was synthesized by powder metallurgical reaction in an evacuated silica tube at 1073 K for 14 days.

Francois et al. (1990) investigated the occurrence of  $\text{CeNiSi}_2$  type for samarium–manganese–germanium combinations for alloys annealed at 1173 K ( $\text{SmMn}_{0.40}\text{Ge}_2$ ;  $a=0.4194$ ,  $b=1.633$ ,  $c=0.4062$ ).

#### 4.7.2. Sm–Fe–Ge

Phase equilibria in the isothermal sections at 870 K (0–40 at.% Sm) and 670 K (40–100 at.% Sm) have been determined by Mruz (1988) using X-ray powder diffraction and partly microstructural analyses of 202 ternary alloys synthesized by arc melting ingots of Sm (99.77 mass%), Fe (99.90 mass%) and Ge (99.99 mass%); the alloys were then annealed in evacuated quartz tubes for 500–900 hours. The total number of compounds observed was nine. The  $\text{Sm}_5\text{Ge}_3$  binary compound was found to dissolve up to 8 at.% Fe. Solubility of the third component in the binary compounds was reported to be negligible. Phase equilibria in the isothermal sections at 870 K and 670 K are presented in fig. 74.

Fig. 74. Sm–Fe–Ge, isothermal sections at 870 K (0–40 at.% Sm) and 670 K (40–100 at.% Sm).

The  $\text{SmFe}_6\text{Ge}_6$  (2) compound was observed and studied by Mruz et al. (1984). It was found to crystallize with  $\text{YCo}_6\text{Ge}_6$  type with lattice parameters  $a=0.5135$ ,  $c=0.4091$  by X-ray powder diffraction of an arc melted alloy annealed at 870 K.

The formation and crystal structure of  $\text{SmFe}_2\text{Ge}_2$  (3) was reported in an early investigation of samarium–iron–germanium combinations by Mruz et al. (1983):  $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4005$ ,  $c=1.0476$  (arc melted sample annealed at 870 K; X-ray powder diffraction data) later confirmed by Bara et al. (1990),  $a=0.4010$ ,  $c=1.0491$ .

Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{SmFe}_{1-x}\text{Ge}_2$  (7) compound by X-ray single-crystal analysis of an arc melted sample annealed at 870 K. The  $\text{CeNiSi}_2$ -type structure was established with lattice parameters  $a=0.4188$ – $0.4198$ ,  $b=1.6208$ – $1.6232$ ,  $c=0.4058$ – $0.4079$ . Francois et al. (1990) confirmed the crystal structure of  $\text{SmFe}_{0.52}\text{Ge}_2$  ( $\text{CeNiSi}_2$  type,  $a=0.4195$ ,  $b=1.619$ ,  $c=0.4076$ ). The sample was prepared by powder metallurgical reaction and annealed in an evacuated silica tube at 1173 K.

The crystal structures of three compounds within the Sm–Fe–Ge system at 870 K were determined by Mruz (1988):  $\text{Sm}_4\text{Fe}_{0.64}\text{Ge}_7$  (8) with  $\text{Sm}_4\text{CoGe}_7$ -type structure,  $a=0.4161$ ,  $b=0.4067$ ,  $c=3.021$ ;  $\text{Sm}_{117}\text{Fe}_{52}\text{Ge}_{112}$  (9) with  $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$ -type structure,  $a=2.8989$ ; and  $\sim\text{Sm}_5\text{Fe}_3\text{Ge}_{12}$  (6) was found to adopt a new structure type  $a=0.4079$ ,  $b=2.5715$ ,  $c=0.4275$ .

The crystal structures of three more germanides,  $\sim\text{SmFe}_{30}\text{Ge}_{19}$  (1),  $\sim\text{Sm}_3\text{Fe}_2\text{Ge}_9$  (4) and  $\sim\text{Sm}_3\text{Fe}_2\text{Ge}_7$  (5), have not been resolved.

The  $\text{SmFe}_{0.67}\text{Ge}_{1.33}$  compound was found to adopt the  $\text{AlB}_2$  type ( $a=0.4141$ ,  $c=0.4092$ ; X-ray powder diffraction) (Felner et al. 1972). This compound was not observed at 870 K by Mruz (1988) in the course of studying the phase equilibria in this system.

#### 4.7.3. Sm–Co–Ge

Phase equilibria in the isothermal sections at 870 K (0–40 at.% Sm) and 670 K (40–100 at.% Sm) have been determined by Mruz (1988) using X-ray powder diffraction and microstructural analyses of 342 ternary alloys synthesized by arc melting ingots of Sm (99.77 mass%), Co (99.90 mass%) and Ge (99.99 mass%). The alloys were annealed in evacuated quartz tubes for 500–900 hours. The phase relations are characterized by the formation of eighteen ternary compounds and by the existence of rather extended solid solutions originating at  $\text{Sm}_5\text{Ge}_3$  (up to 17.5 at.% Co),  $\text{SmCo}_5$  (up to 15 at.% Ge) and  $\text{SmCo}_3$  (up to 10 at.% Ge). Phase equilibria in the isothermal sections at 870 K and 670 K are presented in fig. 75.

Méot-Meyer et al. (1985a) reported the crystal structure of  $\text{SmCo}_{0.71}\text{Ge}_2$  (8) ( $\text{CeNiSi}_2$  type,  $a=0.4169$ ,  $b=1.649$ ,  $c=0.4097$ ). The sample was prepared by powder metallurgical reaction and annealed in evacuated silica tube at 1173 K. Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{SmCo}_{0.72-0.56}\text{Ge}_2$  compound by X-ray powder analysis of arc melted alloys annealed at 870 K alloys. The  $\text{CeNiSi}_2$ -type structure was confirmed ( $a=0.4174$ – $0.4169$ ,  $b=1.6542$ – $1.6395$ ,  $c=0.4122$ – $0.4069$ ).

Fig. 75. Sm–Co–Ge, isothermal sections at 870 K (0–40 at.% Sm) and 670 K (40–100 at.% Sm).

The formation and crystal structure of  $\text{SmCo}_2\text{Ge}_2$  (2) was reported in an early investigation of samarium–cobalt–germanium combinations by Mruz et al. (1983):  $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4016$ ,  $c=1.0133$  (arc melted sample annealed at 870 K; X-ray single-crystal diffraction data).

$\text{Sm}_2\text{Co}_3\text{Ge}_5$  (3) was found to crystallize with the  $\text{Lu}_2\text{Co}_3\text{Si}_5$ -type ( $a=1.1244$ ,  $b=1.193$ ,  $c=0.5768$ ,  $\gamma=120.2^\circ$ ) by Venturini et al. (1986b) from X-ray powder analysis.

Gorelenko et al. (1984) reported the crystal structure of  $\text{SmCoGe}$  (9) (TiNiSi type,  $a=0.7137$ ,  $b=0.4319$ ,  $c=0.7133$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

$\text{Sm}_3\text{Co}_2\text{Ge}_4$  (11) crystallizes with the  $\text{Tb}_3\text{Co}_2\text{Ge}_4$  type structure,  $a=1.0846$ ,  $b=0.8138$ ,  $c=0.4185$ ,  $\gamma=107.70^\circ$ . The sample was prepared by arc melting and annealing at 873 K for 1450 hours. The starting materials were Sm >99.9 mass%, Co 99.99 mass%, Ge 99.999 mass% (Mruz et al. 1989).

Bodak et al. (1986) reported the crystal structure for  $\text{Sm}_2\text{CoGe}_2$  (15) ( $\text{Sc}_2\text{CoSi}_2$  type,  $a=1.0818$ ,  $b=1.0343$ ,  $c=0.4254$ ,  $\gamma=118.53^\circ$ ; X-ray powder diffraction) from an arc melted sample annealed at 870 K.

Investigating the isothermal section of the Sm–Co–Ge system, Mruz et al. (1987a) observed the  $\text{Sm}_4\text{Co}_{0.64}\text{Ge}_7$  (12) compound which belonged to a new structure type. The crystal structure was investigated by a single-crystal method, the lattice parameters were obtained as  $a=0.4166$ ,  $b=0.4083$ ,  $c=3.018$ .

The crystal structure of three compounds within the Sm–Co–Ge system at 870 K was determined by Mruz (1988):  $\text{Sm}_2\text{Co}_{15.1-14.1}\text{Ge}_{1.9-2.9}$  (1) belongs to the  $\text{Th}_2\text{Zn}_{17}$  type,  $a=0.8425-0.8433$ ,  $c=1.2336-1.2368$ ;  $\text{SmCoGe}_3$  (4) crystallizes with the  $\text{BaNiSn}_3$  type,  $a=$

0.4277,  $c=0.9799$ ; and  $\text{Sm}_5\text{Co}_{3-2.5}\text{Ge}_{12-12.5}$  (7) was observed to form a new structure type with lattice parameters  $a=0.4143-0.4174$ ,  $b=2.5534-2.5597$ ,  $c=0.4216-0.4221$ .

The crystal structures of eight more germanides,  $\sim\text{Sm}_3\text{Co}_2\text{Ge}_8$  (5),  $\sim\text{Sm}_3\text{Co}_2\text{Ge}_7$  (6),  $\sim\text{Sm}_5\text{Co}_4\text{Ge}_6$  (10),  $\sim\text{Sm}_{2.9}\text{Co}_{0.9}\text{Ge}_{4.2}$  (13),  $\sim\text{Sm}_3\text{Co}_2\text{Ge}_3$  (14),  $\sim\text{Sm}_{14}\text{Co}_4\text{Ge}_{11}$  (16),  $\sim\text{Sm}_3\text{CoGe}_2$  (17),  $\sim\text{Sm}_5\text{CoGe}_4$  (18) have not been solved yet.

Mrúz (1988) observed the existence of the  $\text{Sm}_{117}\text{Co}_{52}\text{Ge}_{112}$  compound at 870 K ( $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$  type,  $a=2.8928$ ) which was found to decompose at 670 K. This compound is not shown in fig. 75, since it contains  $\sim 42$  at.% Sm and thus is outside of the composition range of the 870 K isothermal section (0–40 at.% Sm), and as it does not exist at 670 K it does not appear in this isothermal section.

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{Sm}_3\text{Co}_4\text{Ge}_{13}$  compound from a sample prepared by heating a mixture of the starting components in an evacuated quartz tube and homogenizing at 1073 K. Finally the sample was quenched in water. The crystal structure was found to adopt the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8814$ . The purity of the starting components was Sm 99.9 mass%, Co 99.99 mass% and Ge 99.99 mass%.

#### 4.7.4. *Sm-Ni-Ge*

Phase equilibria in the isothermal sections at 870 K (0–40 at.% Sm) and 670 K (40–100 at.% Sm) have been established by Mrúz (1988) using X-ray powder diffraction and microstructural analyses of 247 ternary alloys synthesized by arc melting ingots of Sm (99.77 mass%), Ni (99.99 mass%) and Ge (99.99 mass%); the alloys were then annealed in evacuated quartz tubes for 500–900 hours. The phase relations are characterized by the formation of twelve ternary compounds and by the existence of rather extended solid solutions originating at  $\text{Sm}_5\text{Ge}_3$  (dissolves up to 12.5 at.% Ni),  $\text{SmNi}_5$  (15 at.% Ge) and  $\text{Sm}_2\text{Ni}_{17}$  (15 at.% Ge). Phase equilibria in the isothermal sections at 870 K and 670 K are presented in fig. 76.

$\text{SmNi}_5\text{Ge}_3$  (3) was reported to crystallize with the  $\text{YNi}_5\text{Si}_3$  type,  $a=1.9196$ ,  $b=0.38981$ ,  $c=0.67917$  by Mrúz (1988). The arc melted alloy was annealed at 870 K and investigated by X-ray powder diffraction analysis.

The  $\text{SmNi}_2\text{Ge}_2$  (5) compound was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type of structure,  $a=0.4091$ ,  $c=0.9814$  (Rieger and Parthé 1969b).

$\text{SmNiGe}_3$  (7) with its own structure type ( $a=2.1657$ ,  $b=0.4102$ ,  $c=0.4092$ , X-ray single-crystal analysis) was reported by Bodak et al. (1985). For details of sample preparation and purity of starting materials, see above.

$\text{Sm}_2\text{NiGe}_6$  (8) has been found by Mrúz (1988) from X-ray powder diffraction to be isostructural with the  $\text{Ce}_2\text{CuGe}_6$  type ( $a=0.4062$ ,  $b=0.3995$ ,  $c=2.1496$ ). The sample was prepared by arc melting ingots of the constituting elements and annealing at 870 K for 700 hours. For the purity of starting materials, see above.

Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{SmNi}_{1-0.75}\text{Ge}_2$  (9) compound by X-ray powder analysis of arc melted alloys annealed at 870 K ( $\text{CeNiSi}_2$  type,  $a=0.4147-0.4168$ ,  $b=1.6701-1.6589$ ,  $c=0.4147-0.4105$ ).

Fig. 76. Sm-Ni-Ge, isothermal sections at 870 K (0–40 at.% Sm) and 670 K (40–100 at.% Sm).

Mruz et al. (1987b) reported the crystal structure of  $\text{SmNiGe}$  (10) (TiNiSi type,  $a = 0.7100$ ,  $b = 0.4275$ ,  $c = 0.7301$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 500 hours.

An early investigation of the interaction of germanium with samarium and nickel has shown the existence of the  $\text{SmNi}_{0.6-0.5}\text{Ge}_{1.4-1.5}$  (11) compound with  $\text{AlB}_2$  type,  $a = 0.4125-0.4114$ ,  $c = 0.4101-0.4127$  (Gładyshevsky and Bodak 1965; X-ray powder diffraction).

The crystal structures of five germanides,  $\sim\text{SmNi}_7\text{Ge}_2$  (1),  $\sim\text{SmNi}_6\text{Ge}_2$  (2),  $\sim\text{Sm}_2\text{Ni}_9\text{Ge}_5$  (4),  $\sim\text{Sm}_2\text{Ni}_3\text{Ge}_5$  (6),  $\sim\text{Sm}_3\text{NiGe}_2$  (12) have not been evaluated (Mruz 1988).

One more ternary compound was reported by Bodak et al. (1982) who investigated the crystal structure of  $\text{Sm}_3\text{NiGe}_2$  compound ( $\text{La}_3\text{NiGe}_2$  type,  $a = 1.1605$ ,  $b = 0.4242$ ,  $c = 1.1470$ ) by the powder X-ray diffraction method. Apparently this compound does not exist at 870 K. For sample preparation and purity of starting elements, see  $\text{Y}_3\text{NiGe}_2$  under Y-Ni-Ge.

The  $\text{SmNi}_3\text{Ge}_3$  compound was investigated by the single-crystal method (own structure type,  $a = 0.4070$ ,  $c = 2.5137$ ). The single crystal was obtained from “as-cast” alloy (Mruz 1988). This compound was not observed at 870 K.

#### 4.7.5. Sm-Cu-Ge

No phase diagram is available for the Sm-Cu-Ge system, but five ternary compounds have been found.

Rieger and Parthé (1969a) investigated the occurrence of the  $\text{AlB}_2$ -type structure by means of X-ray powder diffraction of arc melted alloys. The data presented were

$\text{SmCu}_{1-0.67}\text{Ge}_{1-1.33}$  with  $a = 0.4255\text{--}0.4152$ ,  $c = 0.3847\text{--}0.4101$ . Iandelli (1993) confirmed the  $\text{AlB}_2$  type ( $a = 0.4259$ ,  $c = 0.3810$ , X-ray powder analysis) from the  $\text{SmCuGe}$  alloy which was prepared from filings or powders of the metals (samarium 99.7 mass%, copper and germanium 99.99 mass%) mixed and sealed in a tantalum crucible under argon, followed by melting in an induction furnace; afterwards the sample was annealed for 10 days at 1023 K.

Sologub et al. (1995a) reported on the crystal structure of  $\text{Sm}_2\text{CuGe}_6$  alloy prepared by arc melting under argon and annealing at 870 K in an evacuated quartz tube for one week. From X-ray powder analysis, it was shown that this compound has the  $\text{Ce}_2\text{CuGe}_6$ -type structure with  $a = 0.41496$ ,  $b = 0.40275$ ,  $c = 2.1221$ .

Rieger and Parthé (1969b) prepared  $\text{SmCu}_2\text{Ge}_2$  with the  $\text{CeGa}_2\text{Al}_2$ -type of structure,  $a = 0.4088$ ,  $c = 1.0223$ .

Francois et al. (1990) reported the crystal structure of the  $\text{SmCu}_{0.55}\text{Ge}_2$  ( $\text{CeNiSi}_2$  type,  $a = 0.4163$ ,  $b = 1.690$ ,  $c = 0.4028$ ). For sample preparation, see  $\text{LaFeGe}_2$  under La–Fe–Ge.

$\text{Sm}_6\text{Cu}_8\text{Ge}_8$  crystallizes with the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$ -type and lattice parameters  $a = 1.412$ ,  $b = 0.668$ ,  $c = 0.426$  (Hanel and Nowotny 1970).

#### 4.7.6. *Sm–Zn–Ge*

No isothermal section is available for the ternary Sm–Zn–Ge system, however one ternary compound was observed and characterized by Rossi and Ferro (1996).  $\text{SmZn}_{1.5}\text{Ge}_{0.5}$  was found to crystallize with the  $\text{AlB}_2$  type,  $a = 0.4412$ ,  $c = 0.3737$  from X-ray powder diffraction of an induction melted alloy which was annealed at 1070 K for one week. An electronic micrographic examination, as well as microprobe microanalysis, was carried out. The metals employed in the synthesis of samples had a nominal purity of 99.9 mass% for samarium, and 99.999 mass% for other metals.

#### 4.7.7. *Sm–Ru–Ge*

The phase equilibria in the Sm–Ru–Ge system have been investigated by Morozkin et al. (1996) by means of X-ray phase and local X-ray spectral analyses of ternary alloys, which were arc melted and subsequently annealed in evacuated silica tubes at 870 K for 1000 hours and finally quenched in water. Starting materials were Sm 99.98 mass%, Ru 99.99 mass%, Ge 99.99 mass%. According to the phase diagram, six ternary compounds exist within the Sm–Ru–Ge system at 870 K (fig. 77). The system contains an extended region of ternary solid solution based at  $\text{SmRu}_2$ .

Early investigations of the  $\text{SmRu}_2\text{Ge}_2$  (1) compound showed that it had the  $\text{CeGa}_2\text{Al}_2$ -type structure:  $a = 0.4236$ ,  $c = 0.9944$ , after Felner and Nowik (1985) from X-ray powder analysis of an induction melted alloy; and  $a = 0.4238$ ,  $c = 0.9953$  (Francois et al. 1985) from X-ray powder analysis of alloy obtained by powder metallurgical reaction at 1273 K. The starting components were Sm (3N), Ru (4N) and Ge (4N). The crystal structure type was confirmed by Morozkin et al. (1996):  $a = 0.4237$ ,  $c = 0.9918$  from arc melted alloy annealed at 870 K.

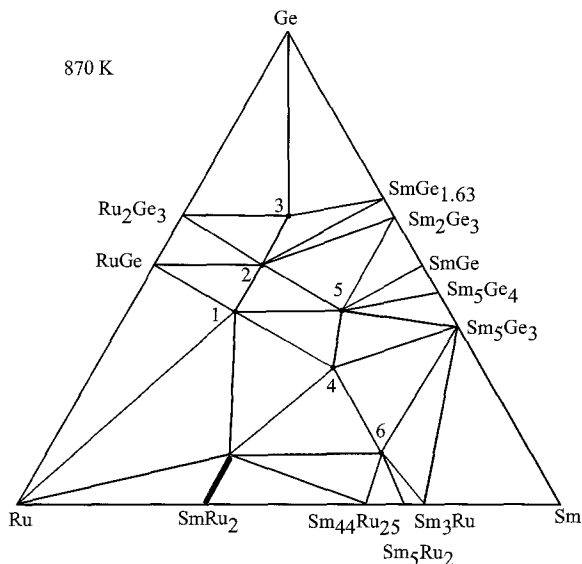

Fig. 77. Sm–Ru–Ge, isothermal section at 870 K.

Venturini et al. (1986b) and Morozkin et al. (1996) reported that the  $\text{Sm}_2\text{Ru}_3\text{Ge}_5$  (2) compound crystallizes with the  $\text{U}_2\text{Co}_3\text{Si}_5$ -type structure. Lattice parameters were reported as  $a=0.9867$ ,  $b=1.244$ ,  $c=0.5790$  (Venturini et al. 1986b; X-ray powder diffraction; for sample preparation, see  $\text{La}_2\text{Ru}_3\text{Ge}_5$  under La–Ru–Ge) and  $a=0.9880$ ,  $b=1.2403$ ,  $c=0.5778$  (Morozkin et al. 1996).

The  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type structure was reported for the  $\text{Sm}_3\text{Ru}_4\text{Ge}_{13}$  compound ( $a=0.9018$ ) by Segre et al. (1981a) from X-ray powder analysis of arc melted samples annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Sm (3N), Ru (3N), Ge (6N). At variance with these data, Morozkin et al. (1996) observed the  $\text{SmRuGe}_3$  (3) compound with the same structure type and lattice parameters  $a=0.9012$  from X-ray powder analysis of arc melted alloy annealed at 870 K.

$\text{Sm}_3\text{Ru}_2\text{Ge}_2$  (4) was found to crystallize with the  $\text{La}_3\text{Ni}_2\text{Ga}_2$ -type structure ( $a=0.5611$ ,  $b=0.7818$ ,  $c=1.3473$ , X-ray powder diffraction) from arc melted samples annealed at 870 K (Bodak et al. 1989a). Morozkin et al. (1996) observed the same structure type and determined the lattice parameters  $a=0.5595$ ,  $b=0.7799$ ,  $c=1.3527$ .

The crystal structure of the  $\text{Sm}_2\text{RuGe}_2$  (5) compound belongs to the  $\text{Zr}_2\text{CoSi}_2$  type,  $a=1.0713$ ,  $b=1.114$ ,  $c=0.413$ ,  $\gamma=129.3^\circ$  (Morozkin et al. 1996).

A compound of unknown structure,  $\text{Sm}_{0.62}\text{Ru}_{0.28}\text{Ge}_{0.10}$  (6), was observed by Morozkin et al. (1996) from a sample annealed at 870 K.

The crystal structure of the  $\text{SmRuGe}$  compound was investigated by Welter et al. (1993b). It was found to adopt the  $\text{PbFCl}$  type,  $a=0.4244$ ,  $c=0.6711$  (X-ray powder diffraction). The compound was prepared from commercially available high-purity elements. A compacted stoichiometric mixture under argon in a sealed silica tube was

heated to 1173 K for preliminary homogenization and then melted in an induction furnace. This compound apparently does not exist at 870 K.

#### 4.7.8. *Sm–Rh–Ge*

The phase equilibria in the Sm–Rh–Ge system have been investigated by Morozkin et al. (1996) by means of X-ray phase and local X-ray spectral analyses of ternary alloys, which were arc melted and subsequently annealed in evacuated silica tubes at 870 K for 1000 hours and finally quenched in water. The starting materials were Sm 99.98 mass%, Rh 99.99 mass%, Ge 99.99 mass% pure. Fourteen ternary compounds were found to exist within the Sm–Rh–Ge system at 870 K (fig. 78). The system contains an extended region of ternary solid solution based at  $\text{SmRh}_2$ .

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{Sm}_3\text{Rh}_4\text{Ge}_{13}$  compound from a sample which was prepared by heating a mixture of starting components in an evacuated quartz tube and homogenized at 1073 K. Finally the sample was quenched in water. The crystal structure was found to adopt the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a = 0.8985$ . The purity of the starting components was Sm 99.9 mass%, Rh 99.99 mass% and Ge 99.99 mass%. Morozkin et al. (1996) observed the homogeneity field for this compound which includes the  $\text{SmRhGe}_3$  composition:  $\text{Sm}_{3+x}\text{Rh}_4\text{Ge}_{13-x}$  ( $x = 0-1$ ) (4),  $a = 0.8969-0.8976$  from X-ray powder analysis of arc melted alloy annealed at 870 K.

Early investigations of the  $\text{SmRh}_2\text{Ge}_2$  (2) compound determined the  $\text{CeGa}_2\text{Al}_2$  type:  $a = 0.4126$ ,  $c = 1.037$  (Francois et al. 1985). For sample preparation, see  $\text{CeRu}_2\text{Ge}_2$  under Ce–Ru–Ge. The structure type for this compound was confirmed later by Morozkin et al. (1996),  $a = 0.4101$ ,  $c = 1.0310$  from arc melted alloy annealed at 870 K.

Fig. 78. Sm–Rh–Ge, isothermal section at 870 K.

$\text{Sm}_2\text{Rh}_3\text{Ge}_5$  (3) was found to crystallize with the  $\text{Lu}_2\text{Co}_3\text{Si}_5$  type ( $a=1.0005$ ,  $b=1.2084$ ,  $c=0.5894$ ,  $\beta=120.2^\circ$ ) by Venturini et al. (1986b) from X-ray powder analysis.

Hovestreydt et al. (1982) reported the crystal structure of the  $\text{SmRhGe}$  (5) compound (TiNiSi type,  $a=0.7074$ ,  $b=0.4371$ ,  $c=0.7468$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. The starting components were Sm (3N), Rh (4N) and Ge (5N). Morozkin et al. (1996) observed the TiNiSi type for the sample annealed at 870 K ( $a=0.7060$ ,  $b=0.4360$ ,  $c=0.7448$ ).

Gladyshevsky et al. (1991a) reported on the crystal structure for the  $\text{Sm}_3\text{Rh}_2\text{Ge}_2$  (6) compound ( $\text{La}_3\text{Ni}_2\text{Ge}_2$  type,  $a=0.5608$ ,  $b=0.7933$ ,  $c=1.3332$ ; X-ray powder diffraction). For the details of sample preparation, see  $\text{La}_3\text{Rh}_2\text{Ge}_2$  under La–Rh–Ge. Morozkin et al. (1996) observed the same structure type and lattice parameters  $a=0.5592$ ,  $b=0.7895$ ,  $c=1.3293$  from X-ray powder diffraction.

Studying this phase diagram, Morozkin et al. (1996) established the crystal structure for  $\text{SmRh}_5\text{Ge}_3$  (1) ( $\text{UCo}_5\text{Si}_3$  type,  $a=1.5848$ ,  $c=0.3679$ ),  $\text{SmRh}_{1-x}\text{Ge}_{2+x}$  (9) ( $\text{CeRh}_{1-x}\text{Ge}_{2+x}$  type,  $a=0.4225$ ,  $b=0.4304$ ,  $c=1.507$ ),  $\text{Sm}_{33}\text{Rh}_{25-20}\text{Ge}_{42-47}$  (8) ( $\text{AlB}_2$  type,  $a=0.4219$ – $0.4208$ ,  $c=0.4017$ – $0.4025$ ),  $\text{Sm}_2\text{RhGe}_2$  (7) ( $\text{Zr}_2\text{CoSi}_2$  type,  $a=1.065$ ,  $b=1.118$ ,  $c=0.4106$ ,  $\gamma=129.96^\circ$ ) and for  $\text{Sm}_2\text{RhGe}_6$  (10) ( $\text{Ce}_2\text{CuGe}_6$  type,  $a=0.4060$ ,  $b=0.4008$ ,  $c=2.190$ ). In addition they observed four compounds with an unknown structure:  $\sim\text{Sm}_{0.33}\text{Rh}_{0.53}\text{Ge}_{0.14}$  (11),  $\sim\text{SmRh}_2\text{Ge}$  (12),  $\sim\text{Sm}_{0.18}\text{Rh}_{0.64}\text{Ge}_{0.18}$  (13),  $\sim\text{SmRh}_3\text{Ge}_6$  (14).

Verniere et al. (1995) mentioned the existence of  $\text{Sm}_4\text{Rh}_{13}\text{Ge}_9$  compound with the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$  type. No lattice parameters were given. For the experimental procedure, see  $\text{La}_4\text{Ir}_{13}\text{Ge}_9$  under La–Ir–Ge. This compound was not observed by Morozkin et al. (1996) in the investigation of phase equilibria in the Sm–Rh–Ge system at 870 K.

#### 4.7.9. Sm–Pd–Ge

A systematic study of the Sm–Pd–Ge system at 870 K was performed by Barakatova (1994) over the whole concentration region by means of X-ray powder and single-crystal analyses as well as using metallography and microprobe analyses. The samples were prepared by arc melting under argon and annealing in evacuated quartz ampoules at 870 K for 1000 hours.

The phase-field distribution in the isothermal section at 870 K (fig. 79) is characterized by existence of ten ternary compounds. Maximum solubilities of germanium in the binary compounds of the Sm–Pd system are 10 at.% for SmPd and 5 at.% for  $\text{SmPd}_{3-2.3}$ . Solubility of samarium in the palladium germanides was found to be negligible. As reported by Barakatova (1994),  $\text{SmPd}_2\text{Ge}_2$  (2) and  $\text{Sm}(\text{Pd},\text{Ge})_2$  (9) dissolve 15 at.% Ge and 10 at.% Ge respectively.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound SmPdGe (8) adopts the  $\text{KHg}_2$ -type of structure,  $a=0.44263$ ,  $b=0.7110$ ,  $c=0.7606$ . For sample preparation, see LaPdGe under La–Pd–Ge. The starting materials were Sm (3N), Pd (4N) and Ge (5N). The existence of SmPdGe was later confirmed by Barakatova (1994) ( $\text{KHg}_2$  type,  $a=0.4426$ ,  $b=0.7110$ ,  $c=0.7606$ ; X-ray powder data).

Fig. 79. Sm–Pd–Ge, isothermal section at 870 K.

The crystal structure of the compound  $\text{SmPd}_2\text{Ge}$  (6) was found to be of the  $\text{YPd}_2\text{Si}$  type ( $a=0.7501$ ,  $b=0.6996$ ,  $c=0.5673$ ; X-ray powder diffraction) by Jorda et al. (1983). For the experimental procedure, see  $\text{LaPd}_2\text{Ge}$  under La–Pd–Ge. The starting materials were palladium 99.99 mass%; germanium, specpure quality; samarium 99.9 mass%. Barakatova (1994) confirmed the structure type and determined the lattice parameters  $a=0.7504$ ,  $b=0.6995$ ,  $c=0.5680$  from X-ray powder analysis.

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Sm}_2\text{PdGe}_6$  (4) compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.4116$ ,  $b=0.4044$ ,  $c=2.170$ . For the experimental procedure, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge. The starting materials used were obtained from Johnson & Matthey, UK (99.9 mass%). The structure type after Barakatova (1994) is the same and lattice parameters are  $a=0.4115$ ,  $b=0.4031$ ,  $c=2.164$ .

During the phase investigation in the Sm–Pd–Ge system, Barakatova (1994) established the crystal structure for  $\text{Sm}_3\text{Pd}_{20}\text{Ge}_6$  (1) ( $\text{Ce}_3\text{Pd}_{20}\text{Ge}_6$  type,  $a=1.242\text{--}1.245$ );  $\text{SmPd}_{2.5\text{--}1.75}\text{Ge}_{1.5\text{--}2.25}$  (2) ( $\text{BaAl}_4$  type,  $a=0.4238\text{--}0.4258$ ,  $c=0.9971\text{--}1.0066$ );  $\text{Sm}_2\text{Pd}_3\text{Ge}_5$  (3) ( $\text{U}_2\text{Co}_3\text{Si}_5$  type,  $a=1.0136$ ,  $b=1.2203$ ,  $c=0.5983$ );  $\text{Sm}_{0.25}\text{Pd}_{0.65}\text{Ge}_{0.10}$  (5) ( $\text{CaTiO}_3$  type,  $a=0.4158$ );  $\text{SmPdGe}_2$  (7) ( $\text{YIrGe}_2$  type,  $a=0.4345$ ,  $b=0.8762$ ,  $c=1.6558$ );  $\text{SmPd}_{0.8\text{--}0.5}\text{Ge}_{1.2\text{--}1.5}$  (9) ( $\text{AlB}_2$  type,  $a=0.4276\text{--}0.4216$ ,  $c=0.3669\text{--}0.4115$ ); and  $\text{Sm}_2\text{PdGe}$  (10) ( $\text{FeB}$  type,  $a=0.8453$ ,  $b=0.3732$ ,  $c=0.5582$ ).

#### 4.7.10. Sm–Ag–Ge

Information on interaction of samarium with silver and germanium is due to the work of three groups of authors (Sologub et al. 1995a, Protsyk 1994, Gibson et al. 1996). The

phase diagram of the Sm–Ag–Ge system is not available; three ternary compounds have been observed and analyzed.

The crystal structure of  $\text{Sm}_2\text{AgGe}_6$  was found to be isotypic with  $\text{Ce}_2\text{CuGe}_6$ ,  $a=0.42394$ ,  $b=0.40956$ ,  $c=2.1346$  by Sologub et al. (1995a) who employed X-ray powder diffraction analysis of an arc melted sample which was homogenized by annealing at 873 K for 150 hours.

Protsyk (1994) reported the  $\text{SmAg}_2\text{Ge}_2$  compound with the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4223$ ,  $c=1.1048$ . For sample preparation, see Ce–Ag–Ge.

The crystal structure of the  $\text{SmAgGe}$  compound was investigated by Gibson et al. (1996) with X-ray powder diffraction. It was found to adopt the  $\text{ZrNiAl}$  type with lattice parameters  $a=0.72005$ ,  $c=0.42692$ . The alloy was arc melted and annealed at 970 K for 10 days.

#### 4.7.11. Sm–Os–Ge

No phase diagram is available at present for the system Sm–Os–Ge, however, one ternary germanide has been observed and characterized by Segre et al. (1981a).  $\text{Sm}_3\text{Os}_4\text{Ge}_{13}$  was found to crystallize with the  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.9043$ . For sample preparation, see  $\text{Ce}_3\text{Ru}_4\text{Ge}_{13}$  under Ce–Ru–Ge.

#### 4.7.12. Sm–Ir–Ge

Phase relations have not been established for the Sm–Ir–Ge system; information concerning the formation of compounds and their crystal structure is due to the work of different groups of authors.

Francois et al. (1987) reported the crystal structure of  $\text{SmIrGe}_2$  (YIrGe<sub>2</sub> type,  $a=0.4314$ ,  $b=1.603$ ,  $c=0.8871$ ). The sample was prepared by heating a mixture of powders of the starting components (Sm 3N, Ir 3N and Ge 3N) in an evacuated silica tube at 1173 K.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound  $\text{SmIrGe}$  adopts the  $\text{TiNiSi}$ -type structure,  $a=0.7017$ ,  $b=0.4346$ ,  $c=0.7557$ . For the experimental procedure, see  $\text{LaIrGe}$  under La–Ir–Ge.

$\text{SmIr}_2\text{Ge}_2$  was found to crystallize in the  $P4/nmm$  space group with lattice parameters  $a=0.4203$ ,  $c=1.0084$  (Francois et al. 1985).

$\text{Sm}_2\text{Ir}_3\text{Ge}_5$  was found to adopt the  $\text{U}_2\text{Co}_3\text{Si}_5$ -type structure ( $a=1.0151$ ,  $b=1.182$ ,  $c=0.6005$ ) by Venturini et al. (1986b) from X-ray powder analysis.

Verniere et al. (1995) observed the existence of  $\text{Sm}_4\text{Ir}_{13}\text{Ge}_9$  with  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type. The lattice parameters have not been established. For the experimental details, see  $\text{La}_4\text{Ir}_{13}\text{Ge}_9$  under La–Ir–Ge.

Venturini et al. (1985b) reported on the X-ray powder diffraction study of the  $\text{Sm}_3\text{Ir}_4\text{Ge}_{13}$  compound from a sample which was prepared by heating a mixture of the starting components (Sm 3N, Ir 4N, Ge 4N) in an evacuated quartz tube and homogenizing at 1073 K. The crystal structure was found to adopt the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.9012$ .

Fig. 80. Sm–Pt–Ge, isothermal section at 870 K.

#### 4.7.13. Sm–Pt–Ge

A systematic study of the Sm–Pt–Ge system at 870 K was performed by Barakatova (1994) over the whole concentration region by means of X-ray powder and single-crystal analyses as well as using metallography and microprobe analyses of 158 alloys. The samples were prepared by arc melting under argon and annealing in evacuated quartz ampoules at 870 K for 1000 hours.

The phase-field distribution in the isothermal section at 870 K (fig. 80) is characterized by the existence of 21 ternary compounds. The maximum solubility of germanium in the binary compounds of Sm–Pt is not indicated by the author. The solubility of samarium in the palladium germanides was found to be negligible.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound SmPtGe (18) adopts the TiNiSi-type of structure,  $a=0.7144$ ,  $b=0.4396$ ,  $c=0.7585$ . For sample preparation, see LaPdGe under La–Pd–Ge. The starting materials were Sm (3N), Pt (4N) and Ge (5N). At variance with these data, Barakatova (1994) observed the SmPtGe compound with the KHg<sub>2</sub> type, lattice parameters  $a=0.4377$ ,  $b=0.7114$ ,  $c=0.7573$ , from X-ray powder analysis of arc melted alloy annealed at 870 K.

Sologub et al. (1995a) reported on the X-ray powder analysis of the Sm<sub>2</sub>PtGe<sub>6</sub> (14) compound which was found to crystallize with the Ce<sub>2</sub>CuGe<sub>6</sub> type,  $a=0.40955$ ,  $b=0.40412$ ,  $c=2.1871$ . For the experimental procedure, see La<sub>2</sub>PdGe<sub>6</sub> under La–Pd–Ge. The starting materials used were obtained from Johnson & Matthey, UK (99.9 mass%).

Venturini et al. (1989a) investigated the crystal structure of SmPt<sub>2</sub>Ge<sub>2</sub> (11) from an arc melted sample annealed at 1273 K for 5 days. The crystal structure was found to

belong to the  $\text{LaPt}_2\text{Ge}_2$  type,  $a=0.4345$ ,  $b=0.4378$ ,  $c=0.9751$ ,  $\beta=91.02^\circ$ . The starting materials were Sm (3N), Pt (4N) and Ge (4N).

Francois et al. (1987) mentioned the existence of  $\text{SmPtGe}_2$  (17) with the  $\text{YIrGe}_2$ -type of structure. No lattice parameters were given. Barakatova (1994) confirmed the crystal structure and established the lattice parameters  $a=0.4367$ ,  $b=0.8720$ ,  $c=1.6332$  by X-ray powder analysis.

In the course of phase equilibrium investigation in the Sm–Pt–Ge system, Barakatova (1994) established the crystal structure for  $\text{Sm}_{0.165}\text{Pt}_{0.735}\text{Ge}_{0.1}$  (5) ( $\text{CaCu}_5$  type,  $a=0.5296$ ,  $c=0.4413$ ),  $\text{SmPt}_{2.25}\text{Ge}_{1.75}$  (10) ( $\text{CaBe}_2\text{Ge}_2$  type,  $a=0.4288$ ,  $c=0.9975$ ),  $\text{SmPt}_{1.87}\text{Ge}_{2.13}$  (12) ( $\text{CaBe}_2\text{Ge}_2$  type,  $a=0.4325$ ,  $c=0.9909$ ),  $\text{Sm}_2\text{Pt}_3\text{Ge}_5$  (13) ( $\text{U}_2\text{Co}_3\text{Ge}_5$  type,  $a=0.9874$ ,  $b=1.1987$ ,  $c=0.5731$ ),  $\text{Sm}_3\text{Pt}_4\text{Ge}_6$  (15) ( $\text{Ce}_3\text{Pt}_4\text{Ge}_6$  type,  $a=0.4351$ ,  $b=0.4359$ ,  $c=2.5886$ ),  $\text{SmPt}_2\text{Ge}$  (16) ( $\text{Fe}_3\text{C}$  type,  $a=0.7436$ ,  $b=0.6901$ ,  $c=0.5585$ ),  $\text{SmPt}_{0.35-0.65}\text{Ge}_{1.65-1.35}$  (19) ( $\text{AlB}_2$  type,  $a=0.4252-0.4185$ ,  $c=0.4022-0.4157$ ),  $\text{SmPt}_{0.24}\text{Ge}_{1.76}$  (20) ( $\alpha\text{-ThSi}_2$  type,  $a=0.4147$ ,  $c=1.4131$ ) and  $\text{Sm}_2\text{Pt}_{1-1.6}\text{Ge}_{1-0.4}$  (21) (CrB type,  $a=0.4033-0.3894$ ,  $b=1.0884-1.0760$ ,  $c=0.4287-0.4415$ ).

The formation of eight more ternary phases with unknown structures has been observed by Barakatova (1994) while investigating the isothermal section of the Sm–Pt–Ge system at 870 K. They exist at compositions close to  $\text{Sm}_{0.075}\text{Pt}_{0.625}\text{Ge}_{0.30}$  (1),  $\text{Sm}_{0.075}\text{Pt}_{0.475}\text{Ge}_{0.45}$  (2),  $\text{Sm}_{0.10}\text{Pt}_{0.665}\text{Ge}_{0.235}$  (3),  $\text{Sm}_{0.12}\text{Pt}_{0.58}\text{Ge}_{0.30}$  (4),  $\text{Sm}_{0.165}\text{Pt}_{0.635}\text{Ge}_{0.20}$  (6),  $\text{Sm}_{0.165}\text{Pt}_{0.57}\text{Ge}_{0.265}$  (7),  $\text{Sm}_{0.165}\text{Pt}_{0.525}\text{Ge}_{0.32}$  (8) and  $\text{Sm}_{0.20}\text{Pt}_{0.60}\text{Ge}_{0.20}$  (9).

#### 4.7.14. Sm–Au–Ge

Information on interaction of samarium with gold and germanium is due to the work of two groups of authors (Sologub et al. 1995a and Rossi et al. 1992). The phase diagram of the Sm–Au–Ge system is not available; two ternary compounds have been observed and analyzed.

Sologub et al. (1995a) employed X-ray powder diffraction analysis for investigation the crystal structure of the  $\text{Sm}_2\text{AuGe}_6$  compound from an arc melted sample, which was homogenized by annealing at 873 K for 150 hours. The crystal structure was found to be isotypic with  $\text{Ce}_2\text{CuGe}_6$ ,  $a=0.42394$ ,  $b=0.40956$ ,  $c=2.1346$ .

A ternary compound of samarium with gold and germanium in the stoichiometric ratio 1:1:1 has been identified and studied by means of X-ray and metallographic analyses by Rossi et al. (1992). The  $\text{SmAuGe}$  compound was found to adopt the  $\text{LiGaGe}$  type with lattice parameters  $a=0.4434$ ,  $c=0.7533$ . The sample was prepared by melting the metals (about 99.9 mass% for samarium and 99.99 mass% for gold and germanium) in an induction furnace and annealing at 1070 K for one week.

### 4.8. Eu–d element–Ge systems

#### 4.8.1. Eu–Mn–Ge

No phase diagram exists for the system Eu–Mn–Ge, and only one ternary compound has been observed from induction melted alloy by Felner and Novik (1978). According

to X-ray powder diffraction analysis, the  $\text{EuMn}_2\text{Ge}_2$  compound crystallizes with the  $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4244$ ,  $c=1.075$ .

#### 4.8.2. *Eu-Fe-Ge*

Information on the phase equilibria in the ternary *Eu-Fe-Ge* system is due to the work of Belan (1988) who employed X-ray powder diffraction on samples prepared by arc melting of pure components. The resulting alloys were annealed at 670 K for 300 hours. The equilibrium phase diagram is shown in fig. 81. No ternary compounds were observed.

Fig. 81. *Eu-Fe-Ge*, isothermal section at 670 K.

#### 4.8.3. *Eu-Co-Ge*

The isothermal section of the *Eu-Co-Ge* phase diagram at 670 K was constructed by Oniskovetz et al. (1985). The phase relations are characterized by the formation of three ternary compounds (fig. 82). For details of sample preparation, see *Eu-Fe-Ge*.

The crystal structures of two compounds have been studied by Oniskovetz et al. (1985).  $\text{EuCo}_{2.5}\text{Ge}_{1.5}$  (1) belongs to the  $\text{BaAl}_4$  type,  $a=0.4035$ ,  $c=0.9746$ ;  $\text{EuCoGe}_3$  (2) crystallizes with the  $\text{BaNiSn}_3$  type,  $a=0.4345$ ,  $c=0.9953$  (powder X-ray diffraction data). Venturini et al. (1985b) confirmed the crystal structure for the  $\text{Eu}_3\text{Co}_4\text{Ge}_{13}$  compound from a sample prepared by heating a mixture of the starting components in an evacuated quartz tube and homogenizing at 1073 K. Finally the sample was quenched in water. It was found to adopt the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$ -type structure,  $a=0.8814$  (X-ray powder diffraction data). The purity of the starting components was Eu 99.9 mass%, Co 99.99 mass%, Ge 99.99 mass%.

Fig. 82. Eu–Co–Ge, isothermal section at 670 K.

One more ternary compound with an unknown structure has been observed by Oniskovetz et al. (1985) in the course of phase equilibrium investigation in the Eu–Co–Ge system:  $\text{Eu}_2\text{Co}_{1-1.2}\text{Ge}_{1-0.8}$  (3).

Felner and Novik (1978) observed the formation of the  $\text{EuCo}_2\text{Ge}_2$  compound and investigated its crystal structure:  $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.4035$ ,  $c = 1.046$ . The sample was melted in an induction furnace at about 1870 K under a protective argon atmosphere; afterwards the alloy was homogenized by annealing in the induction furnace at the melting temperature for about 30 min. Starting materials were Eu 99.9 mass%, Co 99.95 mass% and Ge 99.99 mass%. This phase was not observed by Oniskovetz et al. (1985) in the course of phase equilibrium studies in the Eu–Co–Ge system at 670 K.

#### 4.8.4. *Eu–Ni–Ge*

Phase equilibria in the isothermal sections at 670 K have been determined by Belan (1988) using X-ray powder diffraction of alloys which were synthesized by arc melting ingots of Eu (99.81 mass%), Ni (99.99 mass%) and Ge (99.99 mass%); the alloys were then annealed in evacuated quartz tubes at 670 K for 300 hours. The phase relations are characterized by the formation of six ternary compounds and by the existence of rather extended solid solutions originating at  $\text{Eu}_2\text{Ni}_{17}$  (up to 18 at.% Ge),  $\text{EuNi}_5$  (up to 20 at.% Ge) and  $\text{Eu}_3\text{Ge}$  (up to 12 at.% Ni). The phase equilibria in the isothermal section at 670 K are presented in fig. 83.

The formation and crystal structure of  $\text{EuNi}_2\text{Ge}_2$  (2) was reported in an early investigation of europium–nickel–germanium combinations by Bodak et al. (1966):  $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.4086$ ,  $c = 0.9809$  (arc melted and annealed at 670 K sample; X-ray powder diffraction data). Belan (1988) confirmed the crystal structure and determined the lattice parameters  $a = 0.4133$ ,  $c = 1.0126$ .

Fig. 83. Eu–Ni–Ge, isothermal section at 670 K.

According to Oniskovetz et al. (1987), EuNiGe (5) crystallizes with a new structure type,  $a=0.6996$ ,  $b=0.7581$ ,  $c=0.6187$ ,  $\gamma=130.22^\circ$  (X-ray single-crystal data). The alloy was obtained by arc melting of the proper amounts of pure components (Eu 99.81 mass%; Ni 99.99 mass%, Ge 99.99 mass%) followed by annealing in an evacuated quartz tube at 670 K for 300 hours.

Crystal structures for four more ternary compounds have been established by Oniskovetz (1984) and Belan (1988) while investigating the Eu–Ni–Ge isothermal section: EuNi<sub>9</sub>Ge<sub>4</sub> (1) (CeNi<sub>8.5</sub>Si<sub>4.5</sub> type,  $a=0.7957$ ,  $c=1.1793$ ); EuNiGe<sub>3</sub> (3) (BaNiSn<sub>3</sub> type,  $a=0.4437$ ,  $c=0.9891$ ); EuNiGe<sub>2</sub> (4) (CeNiSi<sub>2</sub> type,  $a=0.4244$ ,  $b=1.691$ ,  $c=0.4228$ ); EuNi<sub>0.5–0.35</sub>Ge<sub>1.5–1.65</sub> (6) (AlB<sub>2</sub> type,  $a=0.4184–0.4169$ ,  $c=0.4485–0.4480$ ).

#### 4.8.5. Eu–Cu–Ge

A systematic study of the Eu–Cu–Ge system at 670 K was performed by Belan (1988). For sample preparation, see Eu–Ni–Ge. The starting materials were Eu 99.81 mass%, Cu 99.99 mass% and Ge 99.99 mass%. Four ternary compounds were found; two of them are characterized by the formation of extended homogeneity fields (see fig. 84).

Belan (1988) observed and characterized three of the four existing ternary compounds: EuCu<sub>2.5–1.65</sub>Ge<sub>1.5–2.35</sub> (1) crystallizes with the CeGa<sub>2</sub>Al<sub>2</sub> type,  $a=0.4187–0.4212$ ,  $c=1.0116–1.0336$ ; EuCu<sub>0.8–0.5</sub>Ge<sub>1.2–1.5</sub> (3) was found to adopt the AlB<sub>2</sub> type,  $a=0.4217–0.4218$ ,  $c=0.4432–0.4460$ ; EuCuGe (2) belongs to the TiNiSi type,  $a=0.7342$ ,  $b=0.4372$ ,  $c=0.7550$ . In contrast, Iandelli (1993) reported a CaCuGe type with  $a=2.209$ ,  $b=0.7543$ ,  $c=0.4453$  from X-ray powder diffraction. For the experimental details, see SmCuGe under Sm–Cu–Ge.

Fig. 84. Eu–Cu–Ge, isothermal section at 670 K.

The crystal structure for the  $\text{Eu}_2\text{Cu}_2\text{Ge}$  (4) compound has not yet been resolved (Belan 1988).

#### 4.8.6. *Eu–Zn–Ge*

The only information on the interaction of europium with zinc and germanium is due to the work of Pöttgen (1996) who reported the crystal structure of  $\text{EuZnGe}$  (ZrBeSi type,  $a=0.4372$ ,  $c=0.8604$ ; X-ray powder diffraction).

#### 4.8.7. *Eu–Ru–Ge*

$\text{EuRu}_2\text{Ge}_2$  was found to crystallize with the  $\text{CeGa}_2\text{Al}_2$  type structure. The lattice parameters were reported as  $a=0.4276$ ,  $c=1.0204$  (Francois et al. 1985).

#### 4.8.8. *Eu–Rh–Ge*

No phase diagram is available for the system Eu–Rh–Ge, and so far, only two ternary compounds have been observed and characterized.

According to Venturini et al. (1985b), the  $\text{EuRhGe}_3$  compound crystallizes with the  $\text{BaNiSn}_3$  type,  $a=0.4410$ ,  $c=1.0064$  (X-ray powder diffraction analysis). For sample preparation and purity of starting components, see  $\text{EuCoGe}_3$  under Eu–Co–Ge.

$\text{EuRh}_2\text{Ge}_2$  was found to crystallize with the  $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4164$ ,  $c=1.0601$  (Francois et al. 1985).

#### 4.8.9. *Eu–Pd–Ge*

Little information exists on the Eu–Pd–Ge system; two compounds have been observed and characterized so far.

According to Belan (1988), the EuPdGe crystallizes with the EuNiGe type,  $a=0.6132$ ,  $b=0.7934$ ,  $c=0.7441$ ,  $\gamma=132.64^\circ$  (X-ray powder diffraction data). The alloy was obtained by arc melting the proper amounts of pure components (Eu 99.81 mass%; Pd 99.99 mass%, Ge 99.99 mass%) followed by annealing in an evacuated quartz tube at 670 K for 300 hours and finally quenching in cold water.

The crystal structure of the compound EuPd<sub>2</sub>Ge was found to be of the YPd<sub>2</sub>Si type ( $a=0.7582$ ,  $b=0.6981$ ,  $c=0.5834$ ; X-ray powder diffraction) by Jorda et al. (1983). The sample was obtained by induction heating the pressed powder compacts in a levitation coil under an argon atmosphere, pressure 4 atm. After the rapid reaction in the liquid state the molten sample was dropped into a boron nitride crucible. The alloy was annealed in an evacuated quartz tube for 10 days at 1173 K. Starting materials were palladium 99.99 mass%, germanium in specpure quality, and europium 99.9 mass%.

#### 4.8.10. Eu–Ag–Ge

The phase equilibria for Eu–Ag–Ge in the isothermal section at 670 K have been determined by Protsyk (1994) using X-ray powder diffraction analysis of 80 ternary alloys, which were synthesized by arc melting ingots of Eu (98.9 mass%), Ag (99.9 mass%) and Ge (99.99 mass%). The alloys were annealed in evacuated quartz tubes for 400 hours. The total number of compounds observed was three. The EuAg<sub>2</sub> binary compound was observed to dissolve up to 15 at.% Ge. The solubility of the third component in other binary compounds was reported to be negligible. The phase equilibria in the isothermal sections at 670 K are presented in fig. 85.

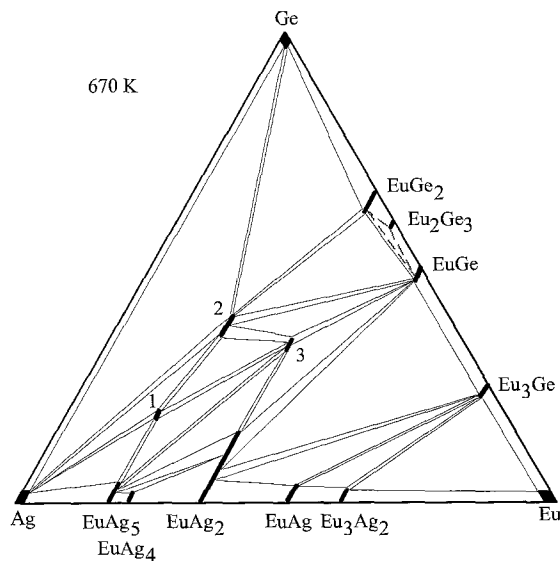

Fig. 85. Eu–Ag–Ge, isothermal section at 670 K.

The  $\text{EuAg}_{2.00-2.25}\text{Ge}_{2.00-1.75}$  (2) compound was observed and studied by Protsyk (1994). It was found to crystallize with the  $\text{CeGa}_2\text{Al}_2$  type, lattice parameters  $a = 0.4300-0.4405$ ,  $c = 1.0787-1.0835$ , by X-ray powder diffraction of arc melted alloys annealed at 470 K.

The formation and crystal structure of the  $\text{EuAgGe}$  (3) compound was investigated by Protsyk (1994):  $\text{AlB}_2$  type,  $a = 0.4364$ ,  $c = 0.4373$  (arc melted sample annealed at 670 K; X-ray powder diffraction data). Merlo et al. (1996) reported a dependence of the crystal structure of the  $\text{EuAgGe}$  system on the thermal treatment. According to micrographic and microprobe analyses, the as-cast sample, prepared on the 1:1:1 formula, contained two phases in nearly equal quantities, with approximate compositions  $\text{EuAg}_{1.1}\text{Ge}_{0.9}$  and  $\text{EuAg}_{0.8}\text{Ge}_{1.1}$ . The X-ray powder pattern was completely indexed as a mixture of reflections of the  $\text{CeCu}_2$ -type cell and an  $\text{AlB}_2$ -type phase. The same sample, annealed at 970 K, showed a prevailing phase with composition  $\text{EuAgGe}_{0.9}$ . Nearly all reflections of the powder pattern were indexed on the basis of the  $\text{CeCu}_2$ -type cell, while some weak lines were ascribed to the  $\text{AlB}_2$ -type cell. The Ag-rich formulae ( $\text{EuAg}_{1.1}\text{Ge}_{0.9}$ ) and Ge-rich formulae ( $\text{EuAg}_{0.8}\text{Ge}_{1.1}$ ) were assigned to the  $\text{CeCu}_2$  type ( $a = 0.4675$ ,  $b = 0.7395$ ,  $c = 0.7981$ ) and the  $\text{AlB}_2$  type ( $a = 0.4390$ ,  $c = 0.4360$ ), respectively.

The crystal structure of  $\text{Eu}_{0.166}\text{Ag}_{0.654}\text{Ge}_{0.18}$  (1) has not been resolved yet (Protsyk 1994).

#### 4.8.11. *Eu-Os-Ge*

No phase diagram is available at present for the system  $\text{Eu-Os-Ge}$ , however, one ternary germanide has been observed and characterized by Segre et al. (1981a).  $\text{Eu}_3\text{Os}_4\text{Ge}_{13}$  was found to crystallize with the  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a = 0.9057$  (Segre et al. 1981a). For sample preparation, see  $\text{Ce}_3\text{Ru}_4\text{Ge}_{13}$  under  $\text{Ce-Ru-Ge}$ .

#### 4.8.12. *Eu-Ir-Ge*

Phase equilibria for the ternary  $\text{Eu-Ir-Ge}$  system have not been derived, however, the formation of two compounds has been observed.

The existence of  $\text{EuIrGe}_3$  has been established by Venturini et al. (1985b). Crystallographic data reported are  $\text{BaNiSn}_3$  type,  $a = 0.4436$ ,  $c = 1.0033$  (X-ray powder diffraction). For details of the experimental procedure, see  $\text{LaCoGe}_3$  under  $\text{La-Co-Ge}$ .

$\text{EuIr}_2\text{Ge}_2$  was found to crystallize with the  $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.4172$ ,  $c = 1.0543$  (Francois et al. 1985).

#### 4.8.13. *Eu-Pt-Ge*

Information on the interaction of europium and platinum with germanium is due to the work of two research groups who employed X-ray powder as well as single-crystal analyses for the investigation of alloys with specific compositions. The phase diagram of the  $\text{Eu-Pt-Ge}$  system is not available.

Venturini et al. (1989a) investigated the crystal structure of  $\text{EuPt}_2\text{Ge}_2$  from an arc melted sample annealed at 1273 K for 5 days. The crystal structure was found to

belong to the  $\text{LaPt}_2\text{Ge}_2$  type,  $a=0.4417$ ,  $b=0.4456$ ,  $c=0.9751$ ,  $\beta=91.27^\circ$  (X-ray powder diffraction data). The starting materials were Eu (3N), Pt (4N) and Ge (4N).

Pöttgen et al. (1996b) investigated the crystal structure of  $\text{EuPtGe}$ : ZrOS type,  $a=0.65463$  (single-crystal X-ray data). The starting materials for the preparation were ingots of europium (Johnson & Matthey), platinum powder (Degussa) and germanium lumps (Wacker), all with stated purity greater than 99.9 mass%. The elements were mixed in the ideal atomic ratio and sealed in a tantalum tube under an argon pressure of about 800 mbar. The tantalum tube was sealed in a quartz ampoule and heated at 1320 K for five days, then cooled to 1170 K and annealed for an additional four weeks.

#### 4.8.14. *Eu–Au–Ge*

Phase relations have not been established for the ternary system  $\text{Eu–Au–Ge}$ ; only one ternary compound has been reported:  $\text{EuAuGe}$  crystallizes in a new ternary ordered version of the  $\text{CeCu}_2$  type,  $a=0.4601$ ,  $b=0.7371$ ,  $c=0.7881$  (single-crystal X-ray data; Pöttgen 1995). For sample preparation, see  $\text{EuPtGe}$  under  $\text{Eu–Pt–Ge}$ .

### 4.9. *Gd–d element–Ge systems*

#### 4.9.1. *Gd–Mn–Ge*

Phase equilibria in the isothermal section at 970 K have been established by Markiv et al. (1993) using X-ray powder diffraction analysis of 103 ternary alloys which were synthesized by arc melting ingots of Gd (99.85 mass%), Mn (99.9 mass%) and Ge (99.999 mass%); the alloys were then annealed in evacuated quartz tubes for 450–550 hours. In some cases the alloys were preliminary homogenized at 1270 K and 1170 K for 10–30 hours. The phase relations are characterized by the formation of nine ternary compounds and by the existence of a solid solution originating at  $\text{GdMn}_2$ . Phase equilibria in the isothermal sections at 970 K are presented in fig. 86.

Information concerning the formation of compounds in the ternary  $\text{Gd–Mn–Ge}$  system is due to the work of several groups of authors; nine ternary compounds have been reported for the various gadolinium–manganese–germanium combinations.

Rossi et al. (1978b) reported on the crystal structure of the  $\text{GdMn}_2\text{Ge}_2$  (4) compound ( $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4029$ ,  $c=1.0895$ ; X-ray powder method). The alloy was obtained by melting under argon in an induction furnace and was annealed at 770 K for one week. The metals used were of purity greater than 99.9 mass% for Gd, and greater than 99.99 mass% for Mn and Ge. The  $\text{CeGa}_2\text{Al}_2$  structure type was confirmed by Belyavina et al. (1993) from X-ray powder diffraction of an arc melted alloy annealed at 970 K ( $a=0.4026$ ,  $c=1.0887$ ).

$\text{GdMn}_6\text{Ge}_6$  (1) was found to crystallize with the  $\text{HfFe}_6\text{Ge}_6$ -type structure by Venturini et al. (1992),  $a=0.5242$ ,  $c=0.8184$  (X-ray powder diffraction data). The alloy was synthesized by a powder metallurgical reaction in an evacuated silica tube at 1073 K for 14 days. Belyavina et al. (1993) suggested a new structure type for the  $\text{GdMn}_6\text{Ge}_6$  compound, which is a derivative from the  $\text{LiCo}_6\text{Ge}_6$  type but with nearly the same lattice parameters:  $a=0.52333$ ,  $c=0.81806$ .

Fig. 86. Gd-Mn-Ge, isothermal section at 970 K.

Francois et al. (1990) investigated the occurrence of the  $\text{CeNiSi}_2$  structure type for several gadolinium-manganese-germanium combinations from alloys annealed at 1173 K:  $\text{GdMn}_{0.26-0.38}\text{Ge}_2$  (5);  $a=0.4138-0.4163$ ,  $b=1.606-1.613$ ,  $c=0.4000-0.4036$ . Belyavina et al. (1993) studied the formation and crystal structure for the  $\text{GdMn}_{0.39}\text{Ge}_2$  compound:  $\text{CeNiSi}_2$  type,  $a=0.41590$ ,  $b=1.6130$ ,  $c=0.4039$ .

Six more ternary compounds were observed and investigated by Belyavina et al. (1993) using X-ray powder diffraction of arc melted alloys annealed at 970 K:  $\text{GdMn}_4\text{Ge}_2$  (3),  $\text{ZrFe}_4\text{Si}_2$  type,  $a=0.76419$ ,  $c=0.39467$ ;  $\text{Gd}_6\text{Mn}_8\text{Ge}_8$  (6),  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$  type,  $a=1.4015$ ,  $b=0.7118$ ,  $c=0.42027$ ;  $\text{GdMnGe}$  (7),  $\text{TiNiSi}$  type,  $a=0.7138$ ,  $b=0.41698$ ,  $c=0.8191$ ;  $\text{Gd}_4\text{Mn}_{0.64}\text{Ge}_7$  (8),  $\text{Sm}_4\text{Co}_{0.64}\text{Ge}_7$  type,  $a=0.4135$ ,  $b=0.4045$ ,  $c=3.0030$ ;  $\text{GdMn}_6\text{Ge}_3$  (2), unknown structure; and  $\text{Gd}_3\text{Mn}_2\text{Ge}_3$  (9), unknown structure.

#### 4.9.2. Gd-Fe-Ge

Four ternary compounds were found in the Gd-Fe-Ge system.

$\text{GdFe}_6\text{Ge}_6$  was reported to be isotypic with the crystal structure of  $\text{YCo}_6\text{Ge}_6$ , with lattice parameters  $a=0.5118$ ,  $c=0.4056$  (Starodub and Mruz 1983). The sample was prepared by arc melting the proper amounts of the starting components followed by annealing at 870 K for two weeks. At variance with the data presented by Starodub and Mruz (1983), Venturini et al. (1992), using X-ray powder diffraction data, found that  $\text{GdFe}_6\text{Ge}_6$  crystallized with a new structure type,  $\text{Pnma}$  space group,  $a=6.143$ ,  $b=0.8137$ ,  $c=7.979$ . The alloy was obtained by powder metallurgical reaction in an evacuated silica tube at 1173 K for two weeks.

Pecharsky et al. (1989) reported  $\text{GdFe}_{0.33}\text{Ge}_2$  to crystallize with the  $\text{CeNiSi}_2$  type ( $a = 0.4140$ ,  $b = 1.6017$ ,  $c = 0.4021$ ; X-ray powder analysis). The alloy was arc melted and annealed at 870 K. The purity of the starting materials was greater than 99.9 mass%. Later Francois et al. (1990) investigated the occurrence of the  $\text{CeNiSi}_2$  structure type for several gadolinium–iron–germanium combinations from alloys obtained by powder metallurgical reaction which were afterwards annealed at 1173 K:  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$ ,  $\text{CeNiSi}_2$  type,  $a = 0.4124-0.4156$ ,  $b = 1.606-1.608$ ,  $c = 0.3998-0.4046$ .

The  $\text{GdFe}_2\text{Ge}_2$  compound was investigated by Rossi et al. (1978a) ( $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.3989$ ,  $c = 1.0485$ ) by means of X-ray diffraction. The alloy was obtained by melting under argon in an induction furnace and annealing at 770 K for one week. The metals used were of purity greater than 99.9 mass% (Gd, Fe) and greater than 99.99 mass% (Ge).

Oleksyn (1990) investigated the crystal structure of  $\text{Gd}_{117}\text{Fe}_{52}\text{Ge}_{112}$  by the X-ray powder method ( $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$  type,  $a = 2.8656$ ). The alloy was synthesized by arc melting followed by annealing at 1070 K for 350 h. The starting materials were Gd 99.83 mass%, Fe 99.9 mass%, Ge 99.99 mass%.

#### 4.9.3. *Gd–Co–Ge*

The phase diagram of the Gd–Co–Ge system has not been established; nine ternary compounds have been identified for gadolinium–cobalt–germanium combinations.

Méot-Meyer et al. (1985a) reported the crystal structure of  $\text{GdCo}_{1-x}\text{Ge}_2$ ,  $x = 0.36$  ( $\text{CeNiSi}_2$  type,  $a = 0.4139$ ,  $b = 1.627$ ,  $c = 0.4062$ ). The sample was prepared by powder metallurgical reaction and annealed in evacuated silica tube at 1173 K. Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{GdCo}_{1-x}\text{Ge}_2$  compound by X-ray powder analysis of arc melted alloys annealed at 870 K. The  $\text{CeNiSi}_2$ -type structure was confirmed, and the existence of an extended homogeneity region was established:  $0.3 < x < 0.7$  ( $a = 0.4128-0.4165$ ,  $b = 1.6157-1.6398$ ,  $c = 0.4024-0.4077$ ). Francois et al. (1990) confirmed the existence of the homogeneity field with a slight deviation in concentration ratio:  $\text{GdCo}_{0.24-0.64}\text{Ge}_2$ ,  $\text{CeNiSi}_2$  type,  $a = 0.4113-0.4139$ ,  $b = 1.608-1.627$ ,  $c = 0.3986-0.4062$ . For sample preparation, see  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$  under Gd–Fe–Ge.

The crystal structure of  $\text{Gd}_3\text{Co}_4\text{Ge}_{13}$  ( $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a = 0.8780$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample which was prepared by heating the a compacted mixture of the starting materials (Gd in pieces, 99.9 mass%; Co and Ge in powder, 99.99 mass%) in an evacuated quartz tube at 1073 K. Bodak et al. (1987) reported the  $\text{Y}_3\text{Co}_4\text{Ge}_{13}$ -type structure for the  $\text{Gd}_3\text{Co}_4\text{Ge}_{13}$  compound ( $a = 0.8769$ ; X-ray powder data) from arc melted alloy annealed at 870 K.

Rieger and Parthé (1969b) investigated the formation of the  $\text{GdCo}_2\text{Ge}_2$  compound ( $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.3996$ ,  $c = 1.0096$ ; X-ray powder diffraction).

From X-ray powder analysis of an alloy obtained by powder metallurgical reaction and annealed at 1173 K,  $\text{Gd}_2\text{Co}_3\text{Ge}_5$  was reported to adopt the  $\text{Lu}_2\text{Co}_3\text{Si}_5$ -type structure,  $a = 0.9683$ ,  $b = 1.183$ ,  $c = 0.5750$ ,  $\beta = 91.65^\circ$  (Venturini et al. 1986b).

The crystal structure of the  $\text{GdCo}_6\text{Ge}_6$  compound was reported by Buchholz and Schuster (1981):  $\text{YCo}_6\text{Ge}_6$  type,  $a = 0.5016$ ,  $c = 0.3931$ . The sample was melted under argon in a corundum crucible at 1073–1273 K.

Gorelenko et al. (1984) reported the crystal structure of GdCoGe: TiNiSi type,  $a = 0.6995$ ,  $b = 0.4269$ ,  $c = 0.7253$ ; X-ray powder analysis. The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

Gd<sub>3</sub>Co<sub>2</sub>Ge<sub>4</sub> crystallizes with the Tb<sub>3</sub>Co<sub>2</sub>Ge<sub>4</sub>-type of structure,  $a = 1.0472$ ,  $b = 0.8057$ ,  $c = 0.4177$ ,  $\gamma = 107.84^\circ$ . The sample was prepared by arc melting and annealing at 873 K for 1450 h. The starting materials were Gd >99.9 mass%, Co 99.99 mass%, Ge 99.999 mass% (Mruz et al. 1989).

Gd<sub>2</sub>CoGe<sub>6</sub> is isotypic with Ce<sub>2</sub>CuGe<sub>6</sub>,  $a = 0.3952$ ,  $b = 0.4019$ ,  $c = 2.1471$  (Oleksyn et al. 1991; X-ray powder diffraction data). The sample was melted in an arc furnace and annealed at 1070 K in an evacuated quartz capsule for 400 h. The purity of the starting materials was greater than 99.9 mass%.

Bodak et al. (1986) reported the crystal structure for Gd<sub>2</sub>CoGe<sub>2</sub> (Sc<sub>2</sub>CoSi<sub>2</sub> type,  $a = 1.0647$ ,  $b = 1.0259$ ,  $c = 0.4224$ ,  $\gamma = 118.48^\circ$ ; X-ray powder diffraction) from an arc melted sample annealed at 870 K.

#### 4.9.4. Gd-Ni-Ge

GdNi<sub>5</sub>Ge<sub>3</sub> was reported to crystallize with the YNi<sub>5</sub>Si<sub>3</sub> type,  $a = 1.9072$ ,  $b = 0.3880$ ,  $c = 0.6792$ , by Fedyna et al. (1987). The arc melted alloy, annealed at 870 K, was investigated by X-ray powder diffraction analysis. The starting materials were Gd 99.83 mass%, Ni 99.99 mass% and Ge 99.99 mass%.

The GdNi<sub>2</sub>Ge<sub>2</sub> compound was found to adopt the CeGa<sub>2</sub>Al<sub>2</sub>-type structure,  $a = 0.4063$ ,  $c = 0.9783$  (Rieger and Parthé 1969b).

GdNiGe<sub>3</sub> with the SmNiSi<sub>3</sub>-type of structure ( $a = 2.1545$ ,  $b = 0.4079$ ,  $c = 0.4073$ , X-ray powder diffraction analysis) was reported by Bodak et al. (1985). For details of sample preparation and purity of starting materials, see GdNi<sub>5</sub>Ge<sub>3</sub> under Gd-Ni-Ge.

Bodak et al. (1982) reported on the crystal structure of Gd<sub>3</sub>NiGe<sub>2</sub> from X-ray powder diffraction (La<sub>3</sub>NiGe<sub>2</sub> type,  $a = 1.1450$ ,  $b = 0.4220$ ,  $c = 1.1355$ ). The proper amounts of starting components were arc melted and annealed at 870 K.

Gd<sub>2</sub>NiGe<sub>6</sub> has been found by Oleksyn (1990) from X-ray powder diffraction to be isostructural with Ce<sub>2</sub>CuGe<sub>6</sub> ( $a = 0.3976$ ,  $b = 0.4029$ ,  $c = 2.133$ ). The sample was prepared by arc melting ingots of the constituting elements and annealing at 1070 K for 700 h. For the purity of starting materials, see GdNi<sub>5</sub>Ge<sub>3</sub> under Gd-Ni-Ge.

Pecharsky et al. (1989) investigated the formation and crystal structure of the GdNi<sub>0.95</sub>Ge<sub>2</sub> compound by X-ray powder analysis of arc melted alloys annealed at 870 K (CeNiSi<sub>2</sub> type,  $a = 0.4128$ ,  $b = 1.674$ ,  $c = 0.4129$ ). For sample preparation, see GdFe<sub>1-x</sub>Ge<sub>2</sub> under Gd-Fe-Ge. Francois et al. (1990) observed the formation of a homogeneity field for this compound: GdNi<sub>0.40-0.95</sub>Ge<sub>2</sub>, CeNiSi<sub>2</sub> type,  $a = 0.4124-0.4128$ ,  $b = 1.628-1.674$ ,  $c = 0.4009-0.4129$ .

GdNi<sub>0.7-0.6</sub>Ge<sub>1.3-1.4</sub> crystallizes with the AlB<sub>2</sub> type,  $a = 0.4111-0.4101$ ,  $c = 0.4033-0.4053$  (Contardi et al. 1977).

Gorelenko et al. (1984) reported the crystal structure of GdNiGe: TiNiSi type,  $a = 0.7009$ ,  $b = 0.4280$ ,  $c = 0.7283$ ; X-ray powder analysis. The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

#### 4.9.5. *Gd-Cu-Ge*

Five ternary compounds have been found in the Gd-Cu-Ge system.

Rieger and Parthé (1969a) investigated the occurrence of the  $AlB_2$ -type structure by means of X-ray powder diffraction of arc melted alloys. The data presented were for a series of alloys  $GdCu_{1-0.67}Ge_{1-1.33}$  with  $a=0.4228-0.4136$ ,  $c=0.3796-0.4041$ . Iandelli (1993) confirmed the structure type for a GdCuGe sample ( $AlB_2$  type,  $a=0.4241$ ,  $c=0.3755$ , X-ray powder analysis). The alloy was prepared from turnings or powders of metals (gadolinium 99.7 mass%, copper and germanium 99.99 mass%) which were mixed and sealed in a tantalum crucible under argon, melted by induction heating and annealed for 10 days at 1023 K.

$Gd_5Cu_8Ge_8$  crystallizes with its own structure type; the lattice parameters are  $a=1.4000$ ,  $b=0.6655$ ,  $c=0.4223$  (Rieger 1970).

Konyk et al. (1988) investigated the crystal structure of  $Gd_2CuGe_6$  alloy prepared by arc melting under argon and annealed at 870 K in an evacuated quartz tube for 720 h. From X-ray powder analysis a  $Ce_2CuGe_6$ -type was claimed,  $a=0.4003$ ,  $b=0.4120$ ,  $c=2.1096$ .

Rieger and Parthé (1969b) prepared  $GdCu_2Ge_2$  with the  $CeGa_2Al_2$ -type structure,  $a=0.4057$ ,  $c=1.0248$ .

Francois et al. (1990) reported the crystal structure of the  $GdCu_{0.32-0.47}Ge_2$  ( $CeNiSi_2$  type,  $a=0.4118-0.4133$ ,  $b=1.644-1.670$ ,  $c=0.3999-0.4005$ ). For sample preparation, see  $GdFeGe_2$  under Gd-Fe-Ge.

#### 4.9.6. *Gd-Nb-Ge*

The phase diagram of the Gd-Nb-Ge system has not been established.

The existence of a compound  $Gd_2Nb_3Ge_5$  with the  $Ce_2Sc_3Si_4$  type ( $a=0.6998$ ,  $b=1.3552$ ,  $c=0.7184$ ) was reported by Le Bihan et al. (1996a) from X-ray powder diffraction data of arc melted alloy. The starting materials were: Gd and Nb 99.99 mass%, Ge 99.999 mass%.

#### 4.9.7. *Gd-Ru-Ge*

Early investigations of the  $GdRu_2Ge_2$  compound determined the  $CeGa_2Al_2$  type with  $a=0.4057$ ,  $c=0.9895$  (Francois et al. 1985) from X-ray powder analysis of alloy obtained by powder metallurgical reaction at 1273 K. The starting components were Gd (3N), Ru (4N) and Ge (4N).

Venturini et al. (1986b) reported that the  $Gd_2Ru_3Ge_5$  compound crystallizes as the  $U_2Co_3Si_5$ -type. The lattice parameters were established as  $a=0.9840$ ,  $b=1.241$ ,  $c=0.5767$  (X-ray powder diffraction data; for sample preparation, see  $La_2Ru_3Ge_5$  under La-Ru-Ge).

$Pr_3Rh_4Sn_{13}$  type was announced for the  $Gd_3Ru_4Ge_{13}$  compound ( $a=0.8995$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Gd (3N), Ru (3N) and Ge (6N).

Francois et al. (1990) reported the crystal structure of  $\text{GdRu}_{0.23-0.36}\text{Ge}_2$  (CeNiSi<sub>2</sub> type,  $a=0.4146-4170$ ,  $b=1.606-1613$ ,  $c=0.4030-0.4064$ ). For sample preparation, see GdFeGe<sub>2</sub> under Gd-Fe-Ge.

#### 4.9.8. Gd-Rh-Ge

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{Gd}_3\text{Rh}_4\text{Ge}_{13}$  compound from a sample which was prepared by heating mixture of starting components (La 3N, Ru 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to adopt the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8968$ .

Early investigations of the  $\text{GdRh}_2\text{Ge}_2$  compound determined it to have the  $\text{CeGa}_2\text{Al}_2$ -type structure:  $a=0.4127$ ,  $c=1.0142$  (Rossi et al. (1979)).

$\text{Gd}_2\text{Rh}_3\text{Ge}_5$  was found to crystallize with the  $\text{Lu}_2\text{Co}_3\text{Si}_5$  type ( $a=0.9993$ ,  $b=1.2062$ ,  $c=0.5875$ ,  $\beta=91.7^\circ$ ; X-ray powder diffraction data) by Venturini et al. (1986b) from a sample prepared by a powder metallurgical reaction at 1173 K. The purity of the starting materials was greater than 99.9 mass%.

Hovestreydt et al. (1982) reported the crystal structure of the  $\text{GdRhGe}$  compound (TiNiSi type,  $a=0.6993$ ,  $b=0.4329$ ,  $c=0.7511$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. The starting components were Gd (3N), Rh (4N) and Ge (5N).

Gladyshevsky et al. (1991a) reported on the crystal structure for the  $\text{Gd}_3\text{Rh}_2\text{Ge}_2$  compound:  $\text{La}_3\text{Ni}_2\text{Ge}_2$  type,  $a=0.5589$ ,  $b=0.7856$ ,  $c=1.3289$  (X-ray powder diffraction data). For the details of sample preparation, see  $\text{La}_3\text{Rh}_2\text{Ge}_2$  under La-Rh-Ge.

Verniere et al. (1995) observed the existence of  $\text{Gd}_4\text{Rh}_{13}\text{Ge}_9$  with  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type structure. No lattice parameters were reported. For details of sample preparation, see  $\text{La}_4\text{Ir}_{13}\text{Ge}_4$  under La-Ir-Ge.

Francois et al. (1990) found a homogeneity field for the compound  $\text{GdCo}_{0.24-0.37}\text{Ge}_2$ , CeNiSi<sub>2</sub> type,  $a=0.4145-0.4169$ ,  $b=1.610-1.622$ ,  $c=0.4010-0.4054$ . For sample preparation, see GdFe<sub>0.25-0.46</sub>Ge<sub>2</sub> under Gd-Fe-Ge.

Venturini et al. (1984) observed the existence of the  $\text{Gd}_5\text{Rh}_4\text{Ge}_{10}$  compound with the  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$  type from a sample which was obtained by heating in an evacuated tube at 1073 K.

#### 4.9.9. Gd-Pd-Ge

No systematic study of the Gd-Pd-Ge system has been performed, but the existence of five ternary compounds has been established by different groups of authors.

The existence of the  $\text{GdPd}_2\text{Ge}_2$  compound ( $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4255$ ,  $c=1.0035$ ) was reported by Rossi et al. (1979). Details of sample preparation are the same as for  $\text{LaPt}_2\text{Ge}_2$ .

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Gd}_2\text{PdGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$  type,  $a=0.40953$ ,  $b=0.40320$ ,  $c=2.1624$ . For the experimental procedure, see  $\text{La}_2\text{PdGe}_6$  under La-Pd-Ge. The starting materials used were obtained from Johnson & Matthey, UK (99.9 mass%).

The crystal structure of the compound  $\text{GdPd}_2\text{Ge}$  was observed to be of the  $\text{YPd}_2\text{Si}$  type,  $a=0.7431$ ,  $b=0.7014$ ,  $c=0.5607$  (X-ray powder diffraction), by Jorda et al. (1983). For the experimental procedure, see  $\text{LaPd}_2\text{Ge}$  under  $\text{La-Pd-Ge}$ . The starting materials were palladium 99.99 mass%; germanium in specpure quality, and gadolinium 99.9 mass%.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound  $\text{GdPdGe}$  adopts the  $\text{KHg}_2$ -type structure,  $a=0.44406$ ,  $b=0.7054$ ,  $c=0.7577$ . For sample preparation, see  $\text{LaPdGe}$  under  $\text{La-Pd-Ge}$ . The starting materials were Gd (3N), Pd (4N) and Ge (5N).

Francois et al. (1990) observed the existence of a homogeneity field for the  $\text{GdPd}_{0.30-0.43}\text{Ge}_2$  compound ( $\text{CeNiSi}_2$  type,  $a=0.4131-0.4154$ ,  $b=1.630-1.648$ ,  $c=0.4033-0.4063$ ). For sample preparation, see  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$  under  $\text{Gd-Fe-Ge}$ .

#### 4.9.10. *Gd-Ag-Ge*

No ternary phase diagram has been established for the  $\text{Gd-Ag-Ge}$  system, however five ternary compounds have been characterized.

$\text{GdAgGe}_3$  was found to crystallize with a new structure type ( $a=3.478$ ,  $b=0.8313$ ,  $c=0.8113$ ; X-ray single-crystal method) by Anisimova et al. (1992). The single crystal was isolated from a sample which was arc melted and annealed at 870 K for two weeks. The purity of the starting materials was greater than 99.9 mass%.

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Gd}_2\text{AgGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$  type,  $a=0.41946$ ,  $b=0.40583$ ,  $c=2.1166$ . For the experimental procedure, see  $\text{La}_2\text{AgGe}_6$  under  $\text{La-Ag-Ge}$ . The starting materials used were obtained from Johnson & Matthey, UK (99.9 mass%).

Anisimova et al. (1992, 1995) reported the existence of the  $\text{Gd}_6\text{Ag}_8\text{Ge}_8$  ( $\text{Gd}_6\text{Cu}_8\text{Ge}_8$  type) and  $\text{GdAg}_2\text{Ge}_2$  ( $\text{CeGa}_2\text{Al}_2$  type) compounds. No lattice parameters were given.

The crystal structure of the  $\text{GdAgGe}$  compound was first investigated by Zanichchi et al. (1983) by X-ray powder diffraction. It was found to adopt the  $\text{ZrNiAl}$  type with lattice parameters  $a=0.7164$ ,  $c=0.4241$ . Gibson et al. (1996) reported a single-crystal investigation of this compound. The crystal structure was confirmed and lattice parameters were obtained as  $a=0.7154$ ,  $c=0.4237$  using a single crystal which was extracted from an arc melted sample annealed at 970 K for 10 days.

#### 4.9.11. *Gd-Re-Ge*

The only information on the system  $\text{Gd-Re-Ge}$  is due to Francois et al. (1990) who investigated the occurrence of the compound with a  $\text{CeNiSi}_2$  type; no phase diagram is available. The  $\text{GdRe}_{0.25}\text{Ge}_2$  compound was found to adopt the  $\text{CeNiSi}_2$  type with lattice parameters  $a=0.4162$ ,  $b=1.607$ ,  $c=0.4056$  (X-ray powder diffraction data). For sample preparation, see  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$  under  $\text{Gd-Fe-Ge}$ .

#### 4.9.12. *Gd-Os-Ge*

No phase diagram exists for the ternary  $\text{Gd-Os-Ge}$  system; one ternary compound has been observed and studied. The  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type structure was announced for the

Gd<sub>3</sub>Os<sub>4</sub>Ge<sub>13</sub> compound ( $a=0.9025$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Gd (3N), Os (3N) and Ge (6N).

#### 4.9.13. Gd–Ir–Ge

No ternary phase diagram has been established for the Gd–Ir–Ge system, however seven ternary compounds have been characterized.

Venturini et al. (1984) observed the Gd<sub>5</sub>Ir<sub>4</sub>Ge<sub>10</sub> compound with Sc<sub>5</sub>Co<sub>4</sub>Si<sub>10</sub>-type structure from a sample obtained by heating a mixture of the starting components in an evacuated silica tube at 1073 K.

Gd<sub>2</sub>Ir<sub>3</sub>Ge<sub>5</sub> was found to crystallize with the U<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub> type ( $a=1.0127$ ,  $b=1.178$ ,  $c=0.5980$ , X-ray powder diffraction method) by Venturini et al. (1986b) from a sample prepared by a powder metallurgical reaction at 1173 K. The purity of the starting materials was greater than 99.9 mass%.

Venturini et al. (1985b) reported an X-ray powder diffraction study of the Gd<sub>3</sub>Ir<sub>4</sub>Ge<sub>13</sub> compound from a sample which was synthesized by heating a mixture of the starting components (Gd 3N, Ir 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to adopt the Yb<sub>3</sub>Rh<sub>4</sub>Sn<sub>13</sub>-type structure,  $a=0.8981$ .

GdIr<sub>2</sub>Ge<sub>2</sub> was found to crystallize in an orthorhombic structure with lattice parameters  $a=0.4113$ ,  $b=0.4207$ ,  $c=1.0167$  (Francois et al. 1985).

Hovestreydt et al. (1982) reported the crystal structure of the GdIrGe compound (TiNiSi type,  $a=0.6933$ ,  $b=0.4308$ ,  $c=0.7596$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. The starting components were Gd (3N), Ir (4N) and Ge (5N).

Verniere et al. (1995) have mentioned the existence of Gd<sub>4</sub>Ir<sub>13</sub>Ge<sub>9</sub> with Ho<sub>4</sub>Ir<sub>13</sub>Ge<sub>9</sub> type. No lattice parameters were given. For the experimental procedure, see La<sub>4</sub>Ir<sub>13</sub>Ge<sub>9</sub> under La–Ir–Ge.

Francois et al. (1987) reported the crystal structure of the GdIrGe<sub>2</sub> (YIrGe<sub>2</sub> type,  $a=0.4287$ ,  $b=1.600$ ,  $c=0.8845$ ). The sample was prepared by heating mixture of powders of starting components (Gd 3N, Ir 3N, Ge 3N) in an evacuated silica tube at 1173 K.

#### 4.9.14. Gd–Pt–Ge

No phase diagram has been established for the Gd–Pt–Ge system. Four ternary compounds were observed by different authors.

According to an X-ray powder diffraction analysis Hovestreydt et al. (1982) reported the compound GdPtGe to adopt the TiNiSi-type structure,  $a=0.7071$ ,  $b=0.4370$ ,  $c=0.7571$ . For sample preparation, see LaPdGe under La–Pd–Ge.

The existence of the GdPt<sub>2</sub>Ge<sub>2</sub> compound (CeGa<sub>2</sub>Al<sub>2</sub> type,  $a=0.436$ ,  $c=0.977$ ) was reported by Rossi et al. (1979). For sample preparation see LaMn<sub>2</sub>Ge<sub>2</sub> under La–Mn–Ge. Venturini et al. (1989a) investigated the crystal structure of GdPt<sub>2</sub>Ge<sub>2</sub> from an arc melted sample annealed at 1273 K for 5 days. It was found to belong to the LaPt<sub>2</sub>Ge<sub>2</sub> structure type,  $a=0.4324$ ,  $b=0.4362$ ,  $c=0.9717$ ,  $\beta=91.13^\circ$ . The starting materials were Gd (3N), Pt (4N) and Ge (4N).

Sologub et al. (1995a) reported an X-ray powder analysis of the  $\text{Gd}_2\text{PtGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.40693$ ,  $b=0.40239$ ,  $c=2.1793$ . For sample preparation, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge.

Francois et al. (1987) reported on the existence of the  $\text{GdPtGe}_2$  with  $\text{YIrGe}_2$ -type. No lattice parameters were given. The sample was prepared by heating mixture of powders of starting components (Gd 3N, Pt 3N, Ge 3N) in evacuated silica tube at 1173 K.

#### 4.9.15. *Gd–Au–Ge*

Information on interaction of gadolinium with gold and germanium is due to the work of two groups of authors (Sologub et al. 1995a, Rossi et al. 1992). The phase diagram of the Gd–Au–Ge system is not yet available; two ternary compounds have been observed and analyzed.

Sologub et al. (1995a) employed X-ray powder diffraction analysis for investigation the crystal structure of the  $\text{Gd}_2\text{AuGe}_6$  compound from arc melted samples, which was homogenized by annealing at 873 K for 150 hours. The crystal structure was found to be isotypic with  $\text{Ce}_2\text{CuGe}_6$  compound,  $a=0.41325$ ,  $b=0.40234$ ,  $c=2.1187$ .

A ternary compound of gadolinium with gold and germanium in the stoichiometric ratio 1:1:1 has been identified and studied by means of X-ray and metallographic analyses by Rossi et al. (1992).  $\text{GdAuGe}$  was found to adopt the  $\text{LiGaGe}$  type structure with lattice parameters  $a=0.4432$ ,  $c=0.7418$ . The sample was prepared by melting the metals (about 99.9 mass% for gadolinium and 99.99 mass% for gold and germanium) in an induction furnace and annealing at 1070 K for 1 week.

#### 4.10. *Tb–d element–Ge systems*

##### 4.10.1. *Tb–Cr–Ge*

Brabers et al. (1994) reported the existence of a compound  $\text{TbCr}_6\text{Ge}_6$  with the  $\text{HfFe}_6\text{Ge}_6$  type ( $a=0.5167$ ,  $c=0.8275$ ; X-ray powder diffraction). The sample was prepared by arc melting and subsequent annealing at 1073 K for three weeks in vacuum.

##### 4.10.2. *Tb–Mn–Ge*

A systematic study of the Tb–Mn–Ge system at 870 K was performed by Starodub et al. (1996) over the whole concentration region by means of X-ray powder analysis (fig. 87). The samples were prepared by arc melting under argon and annealed in evacuated quartz ampoules at 870 K for 240 hours. The starting materials were Tb 99.99 mass%, Mn 99.98 mass% and Ge 99.999 mass%.

The phase-field distribution in the isothermal section at 870 K is characterized by existence of four ternary compounds and by the formation of a homogeneity field for the  $\text{TbMn}_{1-x}\text{Ge}_2$  (3) compound. Maximum solubility of manganese in the  $\text{TbGe}_{1.5}$  compound is 5 at.%.

$\text{TbMn}_6\text{Ge}_6$  (1) was found to crystallize in the  $\text{HfFe}_6\text{Ge}_6$ -type structure by Venturini et al. (1992) ( $a=0.5232$ ,  $c=0.8169$ ; X-ray powder diffraction data). The alloy was

Fig. 87. Tb-Mn-Ge, isothermal section at 870 K.

synthesized by powder metallurgical reaction in evacuated silica tube at 1073 K for 14 days. Starodub et al. (1996) suggested the  $\text{YCo}_6\text{Ge}_6$  type structure with lattice parameters  $a = 0.5210$ ,  $c = 0.4066$  (X-ray powder diffraction).

Rossi et al. (1978b) reported on investigation of the crystal structure of the  $\text{TbMn}_2\text{Ge}_2$  (2) compound ( $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.3999$ ,  $c = 1.0850$ ; X-ray powder method). The alloy was obtained by melting under argon in an induction furnace and was annealed at 770 K for one week. The metals used were of purity greater than 99.9 mass% (Tb) and greater than 99.99 mass% (Mn, Ge). Starodub et al. (1996) confirmed the crystal structure and obtained slightly different lattice parameters:  $a = 0.3998$ ,  $c = 1.0775$ .

$\text{TbMn}_{0.33}\text{Ge}_2$  (3) was found to adopt the  $\text{CeNiSi}_2$  type with lattice parameters  $a = 0.4135$ ,  $b = 1.594$ ,  $c = 0.4020$  by Francois et al. (1990) (X-ray powder diffraction data). For sample preparation, see  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$  under Gd-Fe-Ge. Starodub et al. (1996) confirmed the structure type and observed a homogeneity region for the compound with the  $\text{CeNiSi}_2$  type:  $\text{TbMn}_{0.30-0.35}\text{Ge}_2$ ,  $a = 0.4114-0.4202$ ,  $b = 1.5890-1.6017$ ,  $c = 0.3994-0.4160$ .

One more ternary compound was observed and investigated by Starodub et al. (1996):  $\text{Tb}_9\text{Mn}_{10}\text{Ge}_{10}$  (4). It was found to adopt a  $\text{Tm}_9\text{Fe}_{10}\text{Ge}_{10}$ -type structure with lattice parameters  $a = 0.5398$ ,  $b = 1.3317$ ,  $c = 1.3930$ .

The crystal structures of  $\text{TbMnGe}$  ( $\text{TiNiSi}$  type,  $a = 0.7077$ ,  $b = 0.4132$ ,  $c = 0.8166$ ),  $\text{Tb}_3\text{Mn}_4\text{Ge}_4$  ( $\text{Gd}_3\text{Cu}_4\text{Ge}_4$  type,  $a = 1.3901$ ,  $b = 0.7120$ ,  $c = 0.4163$ ), and  $\text{TbMn}_5\text{Ge}_3$  ( $\text{YCo}_5\text{P}_3$  type,  $a = 1.3050$ ,  $b = 0.3904$ ,  $c = 1.1408$ ) were derived using a single-crystal method (Venturini and Malaman 1997). Single crystals of  $\text{TbMnGe}$  and  $\text{Tb}_3\text{Mn}_4\text{Ge}_4$  were extracted from ingots of the corresponding stoichiometry melted in an induction furnace.

The  $\text{TbMn}_5\text{Ge}_3$  compound was synthesized from a stoichiometry mixture of commercially available high-purity elements compacted into pellets, sealed in a silica tube under argon and annealed at 1223 K for 5 days.

#### 4.10.3. *Tb–Fe–Ge*

The phase diagram for the Tb–Fe–Ge system (fig. 88) was investigated by Starodub (1988) by means of metallographic and X-ray phase analyses. Alloys were prepared by arc melting followed by annealing at 870 K for 240 hours. The purity of the starting components was greater than 99.9 mass%. Six ternary compounds were observed.

$\text{TbFe}_6\text{Ge}_6$  (1) was reported to be isotypic with  $\text{YCo}_6\text{Ge}_6$  with lattice parameters  $a = 0.5106$ ,  $c = 0.4055$  (Mruz et al. 1984). The sample was prepared by arc melting the proper amounts of starting components followed by annealing at 870 K for two weeks. At variance with these data, Venturini et al. (1992) using X-ray powder diffraction data found  $\text{TbFe}_6\text{Ge}_6$  to crystallize with the  $\text{TbFe}_6\text{Sn}_6$  type,  $a = 0.8126$ ,  $b = 1.776$ ,  $c = 0.5125$ . The alloy was obtained by powder metallurgical reaction in an evacuated silica tube at 1173 K for two weeks.

Pecharsky et al. (1989) reported  $\text{TbFe}_{0.33}\text{Ge}_2$  (5) to crystallize with the  $\text{CeNiSi}_2$ -type structure ( $a = 0.4123$ ,  $b = 1.5830$ ,  $c = 0.4006$ ; X-ray powder analysis). The alloy was arc melted and annealed at 870 K. The purity of the starting materials was greater than 99.9 mass%. Francois et al. (1990) confirmed the occurrence of the  $\text{CeNiSi}_2$  type for terbium–iron–germanium combinations from the alloys annealed at 1173 K ( $\text{TbFe}_{0.42}\text{Ge}_2$ ;  $a = 0.4135$ ,  $b = 1.591$ ,  $c = 0.4026$ ).

Pecharsky et al. (1987) investigated the crystal structure of  $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$  (6) by the X-ray single-crystal method (own structure type,  $a = 2.8580$ ). The alloy was synthesized

Fig. 88. Tb–Fe–Ge, isothermal section at 870 K.

by arc melting followed by annealing at 1070 K for 350 h. The starting materials were Tb 99.83 mass%, Fe 99.9 mass%, Ge 99.99 mass%.

According to X-ray powder diffraction data,  $\text{TbFe}_2\text{Ge}_2$  (3) was found to be isostructural with the  $\text{CeGa}_2\text{Al}_2$  type, with lattice parameters  $a = 0.3966$ ,  $c = 1.0470$  (Bara et al. 1990). The sample was synthesized by direct melting the high-purity constituent elements (Tb 4N, Fe 3N, Ge 5N) in an arc furnace. After melting, the sample was annealed at 1073 K for 1 week.

Two more ternary compounds with an unknown structure type were observed by Starodub (1988) at 870 K:  $\text{TbFe}_4\text{Ge}_2$  (2) and  $\text{Tb}_2\text{Fe}_4\text{Ge}_3$  (4).

#### 4.10.4. Tb–Co–Ge

The isothermal section of the Tb–Co–Ge system at 870 K over the whole concentration region was derived by Starodub (1988) (fig. 89) employing X-ray and microstructural analyses of alloys which were prepared by arc melting the proper amounts of the high-purity constituent elements. The melted buttons were then annealed in evacuated silica tubes at 870 K for 300 hours. Ten ternary compounds were found to exist.

Méot-Meyer et al. (1985a) reported the crystal structure of  $\text{TbCo}_x\text{Ge}_2$ ,  $x = 0.57$  (7) ( $\text{CeNiSi}_2$  type,  $a = 0.4117$ ,  $b = 1.618$ ,  $c = 0.4043$ ). The sample was prepared by powder metallurgical reaction and annealed in an evacuated silica tube at 1173 K. Pecharsky et al. (1989) confirmed the formation and crystal structure of the  $\text{TbCo}_x\text{Ge}_2$  compound from arc melted alloy annealed at 870 K ( $a = 0.4110$ – $0.4122$ ,  $b = 1.5991$ – $1.6209$ ,  $c = 0.3999$ – $0.4050$ ; X-ray powder analysis).

The crystal structure of  $\text{Tb}_3\text{Co}_4\text{Ge}_{13}$  (2) ( $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a = 0.8764$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample prepared by heating

Fig. 89. Tb–Co–Ge, isothermal section at 870 K.

a compacted mixture of the starting materials (Tb in pieces, 99.9 mass%; Co and Ge in powder, 99.99 mass%) in an evacuated quartz tube at 1073 K. Bodak et al. (1987) reported the  $Y_3Co_4Ge_{13}$  type for  $Tb_3Co_4Ge_{13}$ ,  $a=0.8779$  (X-ray powder data) from arc melted alloy annealed at 870 K.

$TbCo_2Ge_2$  (3) was found to adopt the  $CeGa_2Al_2$ -type structure,  $a=0.3984$ ,  $c=1.0059$  (Starodub 1988; X-ray powder diffraction).

From X-ray powder analysis of an alloy annealed at 1173 K,  $Tb_2Co_3Ge_5$  (4) was reported to adopt the  $Lu_2Co_3Si_5$ -type structure,  $a=0.9649$ ,  $b=1.183$ ,  $c=0.5715$ ,  $\beta=91.8^\circ$  (Venturini et al. 1986b). Starodub (1988) announced the  $U_2Co_3Si_5$ -type structure with unknown lattice parameters for the  $Tb_2Co_3Ge_5$  compound.

The crystal structure of the  $TbCo_6Ge_6$  (1) compound was reported by Buchholz and Schuster (1981) ( $YCo_6Ge_6$  structure type,  $a=0.5106$ ,  $c=0.4055$ ). The sample was melted under argon in a corundum crucible at 1073–1273 K.

Gorelenko et al. (1984) reported the crystal structure of  $TbCoGe$  (8) (TiNiSi type,  $a=0.6955$ ,  $b=0.4242$ ,  $c=0.7271$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

$Tb_3Co_2Ge_4$  (9) crystallizes with a new type of structure,  $a=1.0692$ ,  $b=0.8067$ ,  $c=0.4164$ ,  $\gamma=107.72^\circ$  (X-ray single-crystal data; Starodub et al. 1986). The sample was prepared by arc melting and annealing at 873 K for 240 h.

$Tb_2CoGe_6$  is isotypic with  $Ce_2CuGe_6$  (6),  $a=0.3941$ ,  $b=0.4003$ ,  $c=2.1439$  (Oleksyn et al. 1991; X-ray powder diffraction data). The sample was melted in an arc furnace and annealed at 1070 K in an evacuated quartz capsule for 400 h. The purity of the starting materials was greater than 99.9 mass%.

Bodak et al. (1986) reported an X-ray single-crystal investigation of the compound  $Tb_2CoGe_2$  (10):  $Sc_2CoSi_2$  type,  $a=1.0569$ ,  $b=1.0209$ ,  $c=0.4212$ ,  $\gamma=118.18^\circ$ .

In the course of isothermal section studies, Starodub (1988) observed a compound  $TbCoGe_3$  (5) with unknown structure.

#### 4.10.5. *Tb–Ni–Ge*

Figure 90 represents the isothermal section of the Tb–Ni–Ge phase diagram at 870 K, which was studied by Starodub (1988). The isothermal section was constructed by means of X-ray powder analysis of 234 alloys which were arc melted and subsequently annealed in evacuated silica tubes for 400 h at 870 K and finally quenched in water. The starting materials were Tb 99.99 mass%, Ni 99.98 mass% and Ge 99.99 mass%.

The ternary phase equilibrium diagram is characterized by the existence of ten ternary compounds and by the formation of a substitutional exchange of Ge/Ni in the solid solutions  $Tb_2(Ni_{1-x}Ge_x)_{17}$  and  $Tb(Ni_{1-x}Ge_x)_5$  for  $0 < x < 0.12$ . This behavior corresponds to the solid solution range of Ge in nickel. Nonstoichiometry was observed for  $TbNi_{1-x}Ge_2$ . The binary  $Tb_2Ge_3$  compound dissolves 12 at.% Ni.

$TbNi_5Ge_3$  (1) was reported to crystallize with the  $YNi_5Si_3$  type,  $a=1.9068$ ,  $b=0.3871$ ,  $c=0.6790$  by Koterlyn et al. (1988). The arc melted alloy, annealed at 870 K, was investigated by X-ray powder diffraction analysis. The starting materials were Tb 99.83 mass%, Ni 99.99 mass% and Ge 99.99 mass%.

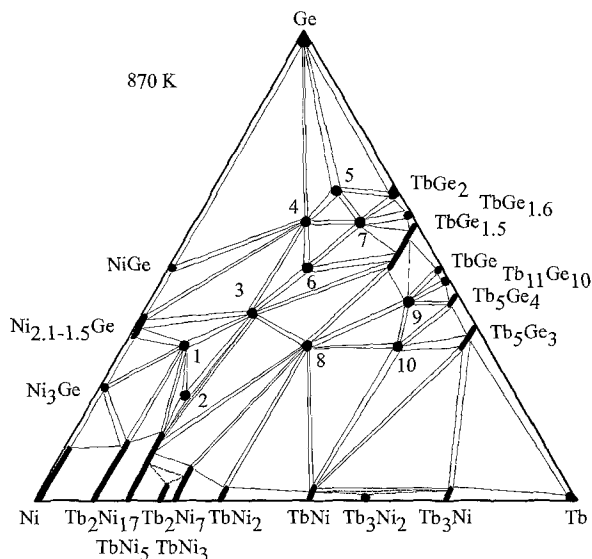

Fig. 90. Tb-Ni-Ge, isothermal section at 870 K

$\text{Tb}_3\text{Ni}_{11}\text{Ge}_4$  (2) belongs to the  $\text{Sc}_3\text{Ni}_{11}\text{Si}_4$  type,  $a=0.8321$ ,  $c=0.8832$ , after Koterlyn et al. (1988). The alloy was prepared in the same manner as  $\text{TbNi}_5\text{Ge}_3$ .

The  $\text{TbNi}_2\text{Ge}_2$  (3) compound was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4044$ ,  $c=0.9782$  (Rieger and Parthé 1969b).

$\text{TbNiGe}_3$  (4) with the  $\text{ScNiSi}_3$ -type structure ( $a=2.1496$ ,  $b=0.4058$ ,  $c=0.4054$ ; X-ray powder diffraction analysis) was reported by Bodak et al. (1985). For the details of sample preparation and purity of starting materials, see  $\text{TbNi}_5\text{Ge}_3$ .

$\text{Tb}_2\text{NiGe}_6$  (5) has been found by Oleksyn (1990) from X-ray powder diffraction to be isostructural with  $\text{Ce}_2\text{CuGe}_6$  ( $a=0.3955$ ,  $b=2.1224$ ,  $c=0.4001$ ). The sample was prepared by arc melting ingots of the constituting elements and annealing at 1070 K for 700 h. For the purity of starting materials, see  $\text{TbNi}_5\text{Ge}_3$ .

Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{TbNi}_{1-x}\text{Ge}_2$  (7) compound by X-ray powder analysis of an arc melted alloy annealed at 870 K ( $\text{CeNiSi}_2$  type,  $a=0.4105$ ,  $b=1.621$ ,  $c=0.3993$ ). For sample preparation, see  $\text{TbNi}_5\text{Ge}_3$ . Francois et al. (1990) confirmed the structure and reported the composition and lattice parameters as  $\text{TbNi}_{0.94}\text{Ge}_2$ ,  $a=0.4096$ ,  $b=1.637$ ,  $c=0.4086$  (X-ray powder diffraction) from a sample obtained by a powder metallurgical reaction at 1173 K.

Gorelenko et al. (1984) reported the crystal structure of  $\text{TbNiGe}$  (8) ( $\text{TiNiSi}$  type,  $a=0.6949$ ,  $b=0.4196$ ,  $c=0.7303$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

Bodak et al. (1982) reported on the crystal structure of  $\text{Tb}_3\text{NiGe}_2$  (10) from X-ray powder diffraction ( $\text{La}_3\text{NiGe}_2$  type,  $a=1.1381$ ,  $b=0.4222$ ,  $c=1.1257$ ). The proper amounts of starting components were arc melted and annealed at 870 K.

The crystal structures of two ternary compounds,  $\text{TbNiGe}_2$  (6) and  $\text{Tb}_{4.75}\text{NiGe}_{4.25}$  (9), have not been evaluated (Starodub 1988).

#### 4.10.6. *Tb–Cu–Ge*

The isothermal section of the  $\text{Tb–Cu–Ge}$  system at 870 K was constructed by Starodub (1988) (fig. 91) as a result of an X-ray powder analysis of 125 alloys. Samples were obtained by arc melting the proper amounts of constituent elements (purity greater than 99.8 mass%) followed by annealing in evacuated quartz tubes at 870 K for 350 h. Finally samples were quenched in ice water. Phase relations are characterized by formation of four ternary compounds. The binary compound  $\text{TbCu}_2$  dissolves about 15 at.% Ge. The existence of an extensive terminal solid solution of  $\text{TbGe}_{1.5}$  which dissolves ~20 at.% Cu, and then shifts in stoichiometry from 1:1.5 to 1:2 as an additional ~10 at.% Cu is added, was observed during the investigation of the phase relations by Starodub (1988).

Rieger and Parthé (1969a) investigated the occurrence of the  $\text{AlB}_2$  type structure by means of X-ray powder diffraction of arc melted alloys. The data presented are  $\text{TbCu}_{1-0.67}\text{Ge}_{1-1.33}$  (4) with  $a = 0.4122\text{--}0.4218$ ,  $c = 0.3976\text{--}0.3744$ . At variance with these data, Iandelli (1993) reported that  $\text{TbCuGe}$  had the  $\text{CaIn}_2$ -type structure ( $a = 0.4247$ ,  $c = 0.7336$ , X-ray powder analysis). The alloy was prepared from turnings or powders of the metals (terbium 99.7 mass%, copper and germanium 99.99 mass%), which were mixed and sealed in a tantalum crucible under argon, melted by induction heating and annealed for 10 days at 1023 K. Starodub (1988) observed the  $\text{AlB}_2$  type for the compound  $\text{TbCu}_{1.0-1.2}\text{Ge}_{1.0-0.8}$  (4),  $a = 0.4234\text{--}0.4225$ ,  $c = 0.3688\text{--}0.3658$ .

$\text{Tb}_6\text{Cu}_8\text{Ge}_8$  (2) crystallizes with the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$  type, and the lattice parameters are  $a = 1.392$ ,  $b = 0.664$ ,  $c = 0.420$  (Hanel and Nowotny 1970). Starodub (1988) confirmed the

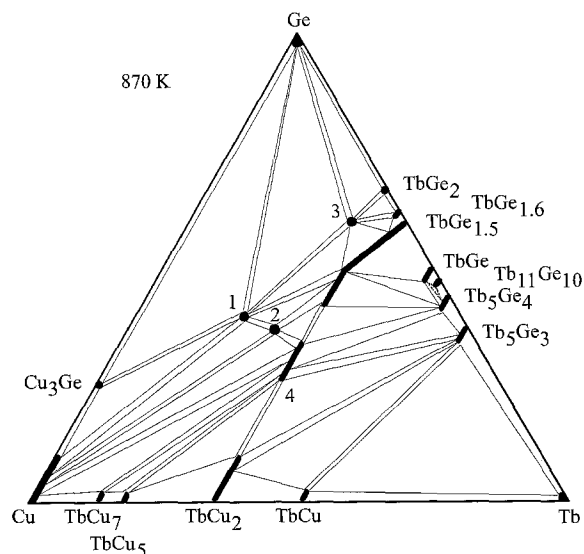

Fig. 91.  $\text{Tb–Cu–Ge}$ , isothermal section at 870 K.

crystal structure of the  $\text{Tb}_6\text{Cu}_8\text{Ge}_8$  compound ( $a=1.3900$ ,  $b=0.6618$ ,  $c=0.4191$ ; X-ray powder diffraction) from an arc melted sample annealed at 870 K.

Konyk et al. (1988) investigated the crystal structure of  $\text{Tb}_2\text{CuGe}_6$  (3) alloy prepared by arc melting under argon and annealed at 870 K in an evacuated quartz tube for 720 h. From X-ray powder analysis the authors concluded that this phase has  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.4000$ ,  $b=0.4113$ ,  $c=2.1010$ .

Rieger and Parthé (1969b) prepared  $\text{TbCu}_2\text{Ge}_2$  (1) with the  $\text{CeGa}_2\text{Al}_2$ -type of structure,  $a=0.4044$ ,  $c=1.0248$ . The existence and crystal structure of this compound was confirmed by Starodub (1988) from an arc melted sample annealed at 870 K.

Francois et al. (1990) observed the  $\text{CeNiSi}_2$  type for the  $\text{TbCu}_{0.39}\text{Ge}_2$  compound and reported lattice parameters  $a=0.4100$ ,  $b=1.648$ ,  $c=0.3995$  (X-ray powder diffraction) from the sample obtained by the powder metallurgical reaction at 1173 K. Apparently this phase does not exist at 870 K.

#### 4.10.7. *Tb-Nb-Ge*

The phase diagram of the *Tb-Nb-Ge* system has not been established. However, the existence of the compound  $\text{Tb}_2\text{Nb}_3\text{Ge}_4$  with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$ -type structure ( $a=0.6981$ ,  $b=1.3515$ ,  $c=0.7156$ ) was reported by Le Bihan et al. (1996a) from X-ray powder diffraction data of an arc melted alloy. Starting materials were Tb and Nb 99.99%, Ge 99.999%.

#### 4.10.8. *Tb-Mo-Ge*

No phase diagram exists for the *Tb-Mo-Ge* system; only one compound was observed and investigated.  $\text{Tb}_2\text{Mo}_3\text{Ge}_4$  was reported to crystallize with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$ -type structure ( $a=0.6921$ ,  $b=1.3149$ ,  $c=0.7062$ ) by Le Bihan et al. (1996b) from X-ray powder diffraction of an arc melted alloy. The starting materials were Tb and Mo 99.99 mass%, Ge 99.999 mass%.

#### 4.10.9. *Tb-Ru-Ge*

Early investigations on the  $\text{TbRu}_2\text{Ge}_2$  compound determined that it had the  $\text{CeGa}_2\text{Al}_2$ -type structure with  $a=0.4221$ ,  $c=0.9879$  (Francois et al. 1985) from X-ray powder analysis of an alloy obtained by powder metallurgical reaction at 1273 K. The starting components were Tb (3N), Ru (4N) and Ge (4N).

Venturini et al. (1986b) reported that the  $\text{Tb}_2\text{Ru}_3\text{Ge}_5$  compound crystallizes with the  $\text{U}_2\text{Co}_3\text{Si}_5$ -type structure. The lattice parameters were reported as  $a=0.9793$ ,  $b=1.241$ ,  $c=0.5742$  (X-ray powder diffraction data). For sample preparation, see  $\text{La}_2\text{Ru}_3\text{Ge}_5$  under *La-Ru-Ge*.

The  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$  type was announced for the  $\text{Tb}_3\text{Ru}_4\text{Ge}_{13}$  compound ( $a=0.8965$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Tb (3N), Ru (3N), Ge (6N).

#### 4.10.10. *Tb–Rh–Ge*

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{Tb}_3\text{Rh}_4\text{Ge}_{13}$  compound from a sample which was prepared by heating a mixture of the starting components (Tb 3N, Rh 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to adopt the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8950$ .

Francois et al. (1985) determined the  $\text{CeGa}_2\text{Al}_2$  type for the  $\text{TbRh}_2\text{Ge}_2$  compound,  $a=0.4118$ ,  $c=1.0280$ .

$\text{Tb}_2\text{Rh}_3\text{Ge}_5$  was found to crystallize with  $\text{Lu}_2\text{Co}_3\text{Si}_5$ -type structure ( $a=0.9951$ ,  $b=1.2046$ ,  $c=0.5849$ ,  $\beta=91.9^\circ$ ; X-ray powder diffraction data) by Venturini et al. (1986b) from a sample prepared by powder metallurgical reaction at 1173 K. The purity of the starting materials was greater than 99.9 mass%.

Hovestreydt et al. (1982) reported the crystal structure of the  $\text{TbRhGe}$  compound (TiNiSi type,  $a=0.6933$ ,  $b=0.4302$ ,  $c=0.7506$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. The starting components were Tb (3N), Rh (4N) and Ge (5N).

Gladyshevsky et al. (1991a) reported on the crystal structure for the  $\text{Tb}_3\text{Rh}_2\text{Ge}_2$  compound ( $\text{La}_3\text{Ni}_2\text{Ge}_2$  type,  $a=0.55627$ ,  $b=0.7808$ ,  $c=1.3233$ ; X-ray powder diffraction data). For the details of sample preparation, see  $\text{La}_3\text{Rh}_2\text{Ge}_2$  under La–Rh–Ge.

Verniere et al. (1995) established that the compound  $\text{Tb}_4\text{Rh}_{13}\text{Ge}_9$  formed the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type structure. No lattice parameters were given. For experimental details, see  $\text{La}_4\text{Ir}_{13}\text{Ge}_9$  under La–Ir–Ge.

Venturini et al. (1984) observed the existence of the  $\text{Tb}_5\text{Rh}_4\text{Ge}_{10}$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure ( $a=1.2970$ ,  $c=0.4285$ ; X-ray powder diffraction) from a sample obtained by heating a mixture of powders in an evacuated tube at 1073 K.

#### 4.10.11. *Tb–Pd–Ge*

No systematic study of the Tb–Pd–Ge system has been performed, but the existence of three ternary compounds has been established by different groups of authors.

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Tb}_2\text{PdGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.40830$ ,  $b=0.40227$ ,  $c=2.1530$ . For the experimental procedure, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge. The starting materials used were obtained from Johnson & Matthey, UK (99.9 mass%).

The crystal structure of the compound  $\text{TbPd}_2\text{Ge}$  was found to be of the  $\text{YPd}_2\text{Si}$  type ( $a=0.7390$ ,  $b=0.7028$ ,  $c=0.5598$ ; X-ray powder diffraction) by Jorda et al. (1983). For the experimental procedure, see  $\text{LaPd}_2\text{Ge}$  under La–Pd–Ge. The starting materials were palladium 99.99 mass%, germanium in specpure quality, and terbium 99.9 mass%.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound  $\text{TbPdGe}$  adopts the  $\text{KHg}_2$ -type of structure,  $a=0.4381$ ,  $b=0.7000$ ,  $c=0.7573$ . For sample preparation, see  $\text{LaPdGe}$  under La–Pd–Ge. The starting materials were Tb (3N), Pd (4N) and Ge (5N).

#### 4.10.12. *Tb–Ag–Ge*

No ternary phase diagram has been established for the Tb–Ag–Ge system, however two ternary compounds have been characterized.

The crystal structure of the  $\text{TbAg}_{0.33}\text{Ge}_{1.67}$  compound has been investigated by Protsyk (1994) by means of X-ray analysis from alloy which was arc melted and annealed in an evacuated silica tube for 500 h at 770 K and finally quenched in water. The starting materials were Tb 99.85 mass%, Ag 99.9 mass% and Ge 99.99 mass%. It was found to adopt the  $\alpha\text{-ThSi}_2$ -type structure with lattice parameters  $a=0.4066$ ,  $c=1.3783$ .

Gibson et al. (1996) reported an X-ray single-crystal investigation of the TbAgGe compound. It was found to adopt the ZrNiAl type,  $a=0.71277$ ,  $c=0.42103$ . The single crystal was extracted from an arc melted sample annealed at 970 K for 10 days.

#### 4.10.13. *Tb–Os–Ge*

No phase diagram exists for the ternary Tb–Os–Ge system, but two ternary compounds have been observed.

$\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type was announced for the  $\text{Tb}_3\text{Os}_4\text{Ge}_{13}$  compound ( $a=0.9002$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Tb (3N), Os (3N) and Ge (6N).

Venturini et al. (1986b) observed the existence of the  $\text{Tb}_2\text{Os}_3\text{Ge}_5$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$  type structure from a sample obtained by heating a mixture of the starting components in an evacuated quartz tube at 1173 K.

#### 4.10.14. *Tb–Ir–Ge*

No ternary phase diagram has been established for the Tb–Ir–Ge system, however eight ternary compounds have been characterized.

Venturini et al. (1984) observed the existence of the  $\text{Tb}_5\text{Ir}_4\text{Ge}_{10}$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$  type,  $a=1.2935$ ,  $c=0.4318$ , from a sample obtained by heating a mixture of the starting components in an evacuated quartz tube at 1073 K.

$\text{Tb}_2\text{Ir}_3\text{Ge}_5$  was found to crystallize with  $\text{U}_2\text{Co}_3\text{Si}_5$ -type structure ( $a=1.0122$ ,  $b=1.276$ ,  $c=0.5790$ , X-ray powder diffraction method) by Venturini et al. (1986b) from a sample prepared by powder metallurgical reaction at 1173 K. The purity of the starting materials was greater than 99.9 mass%.

Venturini et al. (1985b) reported on the X-ray powder diffraction study of the  $\text{Tb}_3\text{Ir}_4\text{Ge}_{13}$  compound from an alloy which was synthesized by heating a mixture of the starting components (Tb 3N, Ir 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to adopt the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8962$ .

$\text{TbIr}_2\text{Ge}_2$  was found to adopt a tetragonal structure with lattice parameters  $a=0.4144$ ,  $c=1.0222$  (Francois et al. 1985).

Hovestreydt et al. (1982) reported the crystal structure for the TbIrGe compound ( $\text{TiNiSi}$  type,  $a=0.6871$ ,  $b=0.4280$ ,  $c=0.7591$ ; X-ray powder data) from an arc melted

sample annealed at 1270 K for 1–2 weeks. The starting components were Tb (3N), Ir (4N) and Ge (5N).

Verniere et al. (1995) announced the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type structure for  $\text{Tb}_4\text{Ir}_{13}\text{Ge}_9$ . No lattice parameters were given. For the experimental procedure, see  $\text{La}_4\text{Ir}_{13}\text{Ge}_9$  under La–Ir–Ge.

Francois et al. (1987) reported the crystal structure of  $\text{TbIrGe}_2$  ( $\text{NdIrGe}_2$  type,  $a = 0.4266$ ,  $b = 1.595$ ,  $c = 0.8829$ ). The sample was prepared by heating a mixture of powders of the starting components (Tb 3N, Ir 3N and Ge 3N) in an evacuated silica tube at 1173 K.

$\text{Tb}_4\text{Ir}_7\text{Ge}_6$  was reported to adopt the  $\text{U}_4\text{Re}_7\text{Si}_6$ -type structure ( $a = 0.8345$ ; Francois et al. 1985) from a sample obtained by heating a mixture of powders of the starting materials (Tb 3N, Os and Ge 4N) in an evacuated quartz tube at 1273 K.

#### 4.10.15. *Tb–Pt–Ge*

No phase diagram has been established for the Tb–Pt–Ge system. Four ternary compounds were observed by different authors.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound  $\text{TbPtGe}$  adopts the  $\text{TiNiSi}$ -type of structure,  $a = 0.7020$ ,  $b = 0.4354$ ,  $c = 0.7564$ . For sample preparation, see  $\text{LaPdGe}$  under La–Pd–Ge.

The existence of the  $\text{TbPt}_2\text{Ge}_2$  compound ( $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.436$ ,  $c = 0.977$ ) was reported by Rossi et al. (1979). For sample preparation see  $\text{LaMn}_2\text{Ge}_2$  under La–Mn–Ge. Venturini et al. (1989a) investigated the crystal structure of  $\text{TbPt}_2\text{Ge}_2$  from an arc melted sample annealed at 1273 K for 5 days. The crystal structure was found to belong to the  $\text{LaPt}_2\text{Ge}_2$  type,  $a = 0.4311$ ,  $b = 0.4351$ ,  $c = 0.9711$ ,  $\beta = 91.09^\circ$ . The starting materials were Tb (3N), Pt (4N) and Ge (4N).

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Tb}_2\text{PtGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$  type,  $a = 0.40634$ ,  $b = 0.40155$ ,  $c = 2.1648$ . For sample preparation, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge.

Francois et al. (1987) mentioned the existence of  $\text{TbPtGe}_2$  with  $\text{YIrGe}_2$ -type structure. No lattice parameters were given. The sample was prepared by heating a mixture of powders of the starting components (Gd 3N, Ir 3N, Ge 3N) in an evacuated silica tube at 1173 K.

#### 4.10.16. *Tb–Au–Ge*

Information on interaction of terbium with gold and germanium is due to the work of two groups of authors (Sologub et al. 1995a and Rossi et al. 1992). The phase diagram of the Tb–Au–Ge system is not yet available; two ternary compounds have been observed and their structures were determined.

Sologub et al. (1995a) employed X-ray powder diffraction analysis for studying the crystal structure of  $\text{Tb}_2\text{AuGe}_6$ . It was found to be isotypic with  $\text{Ce}_2\text{CuGe}_6$ ,  $a = 0.41325$ ,  $b = 0.40234$ ,  $c = 2.1187$ . For the details of sample preparation, see  $\text{Gd}_2\text{AuGe}_6$  under Gd–Au–Ge.

A ternary compound of terbium with gold and germanium in the stoichiometric ratio 1:1:1 has been identified and studied by means of X-ray and metallographic analyses by Rossi et al. (1992). TbAuGe was found to adopt the LiGaGe type with lattice parameters  $a=0.4416$ ,  $c=0.7335$ . For the experimental procedure see GdAuGe under Gd–Au–Ge.

#### 4.11. Dy–d element–Ge systems

##### 4.11.1. Dy–Cr–Ge

The only reference on the Dy–Cr–Ge system is due to Brabers et al. (1994) who reported the existence of a compound DyCr<sub>6</sub>Ge<sub>6</sub> with the HfFe<sub>6</sub>Ge<sub>6</sub> type ( $a=0.5162$ ,  $c=0.8272$ ; X-ray powder diffraction). The sample was prepared by arc melting and subsequent annealing at 1073 K for three weeks in vacuum.

##### 4.11.2. Dy–Mn–Ge

No ternary phase diagram of the Dy–Mn–Ge system is available. Two ternary compounds have been reported for various dysprosium manganese germanium combinations.

DyMn<sub>6</sub>Ge<sub>6</sub> was found to crystallize in the HfFe<sub>6</sub>Ge<sub>6</sub>-type structure by Venturini et al. (1992),  $a=0.5228$ ,  $c=0.8163$  (X-ray powder diffraction data). The alloy was synthesized by a powder metallurgical reaction in an evacuated silica tube at 1073 K for 14 days.

Rossi et al. (1978b) reported on the crystal structure of the DyMn<sub>2</sub>Ge<sub>2</sub> compound (CeGa<sub>2</sub>Al<sub>2</sub> type,  $a=0.3980$ ,  $c=1.0737$ ; X-ray powder method). The alloy was obtained by melting under argon in an induction furnace and annealing at 770 K for a week. The metals used were of purity greater than 99.9 mass% for Dy, and greater than 99.99 mass% for Mn and Ge.

The DyMn<sub>0.33</sub>Ge<sub>2</sub> compound was found to adopt the CeNiSi<sub>2</sub>-type structure with lattice parameters  $a=0.4118$ ,  $b=1.583$ ,  $c=0.4000$  by Francois et al. (1990) (X-ray powder diffraction data). For sample preparation, see GdFe<sub>0.25–0.46</sub>Ge<sub>2</sub> under Gd–Fe–Ge.

##### 4.11.3. Dy–Fe–Ge

No phase diagram has been constructed for the Dy–Fe–Ge system, but six ternary compounds have been found and characterized by different authors.

DyFe<sub>6</sub>Ge<sub>6</sub> was reported to be isotypic with YCo<sub>6</sub>Ge<sub>6</sub> with lattice parameters  $a=0.5108$ ,  $c=0.4044$  (Mruz et al. 1984). The sample was prepared by arc melting of the proper amounts of the starting components followed by annealing at 870 K for two weeks. At variance with these data, DyFe<sub>6</sub>Ge<sub>6</sub> was found to crystallize with the TbFe<sub>6</sub>Sn<sub>6</sub> type,  $a=0.8111$ ,  $b=1.766$ ,  $c=0.5116$  by Venturini et al. (1992) from X-ray powder diffraction data. The alloy was obtained by a powder metallurgical reaction in an evacuated silica tube at 1173 K for two weeks.

Pecharsky et al. (1989) reported DyFe<sub>0.33</sub>Ge<sub>2</sub> to crystallize with the CeNiSi<sub>2</sub>-type structure ( $a=0.4118$ ,  $b=1.5903$ ,  $c=0.4002$ ; X-ray powder analysis). The alloy was arc melted and annealed at 870 K. The purity of the starting materials was greater than

99.9 mass%. Francois et al. (1990) confirmed the crystal structure of this compound,  $a = 0.4121$ ,  $b = 1.581$ ,  $c = 0.4011$  (X-ray powder diffraction data). For sample preparation, see  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$  under Gd–Fe–Ge.

$\text{DyFe}_4\text{Ge}_2$  is isotypic with the crystal structure of  $\text{ZrFe}_4\text{Si}_2$ ;  $a = 0.7303$ ,  $c = 0.3865$  according to Fedyna (1988). The alloy was prepared by arc melting the proper amounts of the starting components followed by annealing at 870 K for 400 hours.

Oleksyn (1990) investigated the crystal structure of  $\text{Dy}_{117}\text{Fe}_{52}\text{Ge}_{112}$  compound by the X-ray powder method ( $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$  type,  $a = 2.8382$ ). The alloy was synthesized by arc melting followed by annealing at 1070 K for 350 h. The starting materials were Dy 99.83 mass%, Fe 99.9 mass%, Ge 99.99 mass%.

According to X-ray powder diffraction,  $\text{DyFe}_2\text{Ge}_2$  was found to be isostructural with the  $\text{CeGa}_2\text{Al}_2$  type,  $a = 0.3957$ ,  $c = 1.0446$  (Rossi et al. 1978a).

$\text{Dy}_6\text{Fe}_8\text{Ge}_8$  has the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$  type structure,  $a = 1.3528$ ,  $b = 0.6793$ ,  $c = 0.4135$  (X-ray powder diffraction; Fedyna et al. 1994).

#### 4.11.4. Dy–Co–Ge

The phase diagram for the Dy–Co–Ge system has not been established. Nine ternary compounds have been identified for various dysprosium–cobalt–germanium combinations.

Méot-Meyer et al. (1985a) reported the crystal structure of the  $\text{DyCo}_{1-x}\text{Ge}_2$ ,  $x = 0.44$  ( $\text{CeNiSi}_2$  type,  $a = 0.4098$ ,  $b = 1.607$ ,  $c = 0.4020$ ). Samples were prepared by powder metallurgical reaction and annealed in an evacuated silica tube at 1173 K. Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{DyCo}_{1-x}\text{Ge}_2$  compound by X-ray powder analysis of arc melted alloys annealed at 870 K. The  $\text{CeNiSi}_2$ -type structure was confirmed with lattice parameters  $a = 0.4130$ – $0.4135$ ,  $b = 1.6045$ – $1.6057$ ,  $c = 0.4026$ – $0.4028$ .

The crystal structure of  $\text{Dy}_3\text{Co}_4\text{Ge}_{13}$  ( $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a = 0.8744$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample which was prepared by heating a compacted mixture of the starting materials (Dy in pieces, 99.9 mass%; Co and Ge in powder, 99.99 mass%) in an evacuated quartz tube at 1073 K. Bodak et al. (1987) reported the  $\text{Y}_3\text{Co}_4\text{Ge}_{13}$  type for the  $\text{Dy}_3\text{Co}_4\text{Ge}_{13}$  compound ( $a = 0.8750$ ; X-ray powder data) from arc melted alloy annealed at 870 K.

From X-ray powder analysis of an alloy annealed at 1173 K,  $\text{Dy}_2\text{Co}_3\text{Ge}_5$  was reported to adopt  $\text{Lu}_2\text{Co}_3\text{Si}_5$ -type structure,  $a = 0.9627$ ,  $b = 1.180$ ,  $c = 0.5707$ ,  $\beta = 91.0^\circ$  (Venturini et al. 1986b).

The crystal structure of the  $\text{DyCo}_6\text{Ge}_6$  compound was reported by Buchholz and Schuster (1981) ( $\text{YCo}_6\text{Ge}_6$  structure type,  $a = 0.5081$ ,  $c = 0.3918$ ). The sample was melted under argon in a corundum crucible at 1073–1273 K.

Gorelenko et al. (1984) reported the crystal structure of  $\text{DyCoGe}$  ( $\text{TiNiSi}$  type,  $a = 0.6886$ ,  $b = 0.4204$ ,  $c = 0.7256$ ; X-ray powder analysis). The alloy was arc melted and annealed in an evacuated quartz tube at 870 K for 350 hours.

$\text{Dy}_3\text{Co}_2\text{Ge}_4$  crystallizes with the  $\text{Tb}_3\text{Co}_2\text{Ge}_4$  type structure,  $a = 1.0590$ ,  $b = 0.8114$ ,  $c = 0.4135$ ,  $\gamma = 107.83^\circ$ . The sample was prepared by arc melting and annealing at

873 K for 1450 h. The starting materials were: Dy >99.9 mass%, Co 99.99 mass%, Ge 99.999 mass% (Mruz et al. 1989).

$\text{Dy}_2\text{CoGe}_6$  is isotypic with  $\text{Ce}_2\text{CuGe}_6$ ,  $a = 0.3931$ ,  $b = 0.3983$ ,  $c = 2.1341$  (Oleksyn et al. 1991, X-ray powder diffraction data). The sample was melted in an arc furnace and annealed at 1070 K in an evacuated quartz capsule for 400 hours. The purity of the starting materials was greater than 99.9 mass%.

Bodak et al. (1986) reported the crystal structure for  $\text{Dy}_2\text{CoGe}_2$  ( $\text{Sc}_2\text{CoSi}_2$  type,  $a = 1.0467$ ,  $b = 1.0132$ ,  $c = 0.4178$ ,  $\gamma = 117.33^\circ$ ; X-ray powder diffraction) from an arc melted sample annealed at 870 K.

#### 4.11.5. Dy–Ni–Ge

Figure 92 represents the isothermal section of the Dy–Ni–Ge phase diagram at 870 K, which was studied by Koterlyn et al. (1988). The isothermal section was constructed by means of X-ray powder analysis of alloys, which were arc melted, subsequently annealed in evacuated silica tubes for 400 h at 870 K, and finally quenched in ice water. The starting materials were Dy 99.99 mass%, Ni 99.98 mass% and Ge 99.99 mass%.

The ternary phase diagram is characterized by the existence of ten ternary compounds and by the formation of a substitutional exchange of Ge/Ni in the Ni terminal solid solutions  $\text{Dy}_2(\text{Ni}_{1-x}\text{Ge}_x)_{17}$  and  $\text{Dy}(\text{Ni}_{1-x}\text{Ge}_x)_5$ . Nonstoichiometry and a homogeneity range were observed for  $\text{DyNi}_{1-x}\text{Ge}_2$  (7). The binary  $\text{Dy}_2\text{Ge}_3$  compound dissolves 20 at.% Ni.

$\text{DyNi}_5\text{Ge}_3$  (1) was reported to crystallize with the  $\text{YNi}_5\text{Si}_3$  type,  $a = 1.9065$ ,  $b = 0.3864$ ,  $c = 0.6787$ , by Fedyna (1988). The arc melted alloy, annealed at 870 K, was investigated

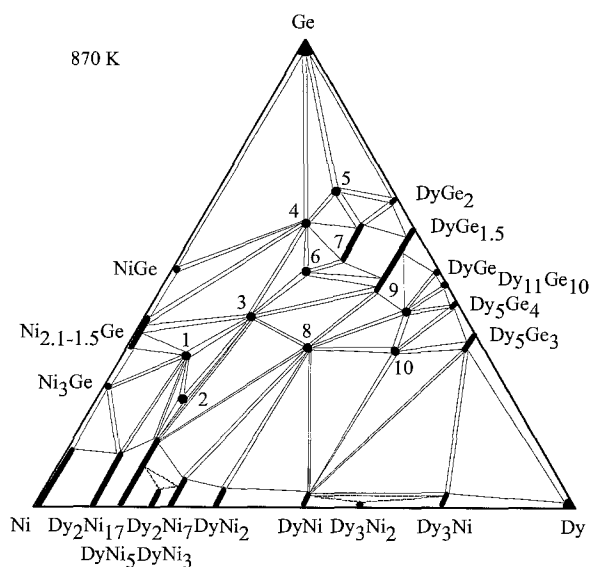

Fig. 92. Dy–Ni–Ge, isothermal section at 870 K.

by X-ray powder diffraction analysis. The starting materials were Dy 99.83 mass%, Ni 99.99 mass%, and Ge 99.99 mass%.

$\text{Dy}_3\text{Ni}_{11}\text{Ge}_4$  (2) belongs to the  $\text{Sc}_3\text{Ni}_{11}\text{Si}_4$  type,  $a=0.8317$ ,  $c=0.8807$ , after Fedyna (1988). For sample preparation, see  $\text{DyNi}_5\text{Ge}_3$  under Dy–Ni–Ge.

The  $\text{DyNi}_2\text{Ge}_2$  (3) compound was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4035$ ,  $c=0.9758$  (Rieger and Parthé 1969b).

$\text{DyNiGe}_3$  (4) with the  $\text{ScNiSi}_3$ -type structure ( $a=2.1430$ ,  $b=0.4054$ ,  $c=0.4042$ , X-ray powder diffraction analysis) was reported by Bodak et al. (1985). For the details of sample preparation and purity of starting materials, see  $\text{DyNi}_5\text{Ge}_3$ , above.

$\text{Dy}_2\text{NiGe}_6$  (5) has been found by Oleksyn (1990) from X-ray powder diffraction to be isostructural with  $\text{Ce}_2\text{CuGe}_6$  ( $a=0.3955$ ,  $b=2.1170$ ,  $c=0.4007$ ). Samples were prepared by arc melting ingots of the constituting elements and annealing at 1070 K for 700 h. For the purity of starting materials, see  $\text{DyNi}_5\text{Ge}_3$ , above.

Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{DyNi}_{1-x}\text{Ge}_2$  (7) compound by X-ray powder analysis of an arc melted alloy annealed at 870 K ( $\text{CeNiSi}_2$  type,  $a=0.4102$ ,  $b=1.6216$ ,  $c=0.4013$ ). For sample preparation, see  $\text{DyFe}_{1-x}\text{Ge}_2$  under Dy–Fe–Ge. Francois et al. (1990) confirmed the structure and reported the composition and lattice parameters  $\text{DyNi}_{0.80}\text{Ge}_2$ ,  $a=0.4093$ ,  $b=1.651$ ,  $c=0.4052$  (X-ray powder diffraction) from a sample obtained by a powder metallurgical reaction at 1173 K.

Gorelenko et al. (1984) reported the crystal structure for  $\text{DyNiGe}$  (8) (TiNiSi type,  $a=0.6963$ ,  $b=0.4213$ ,  $c=0.7285$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

Bodak et al. (1982) reported on the crystal structure for the  $\text{Dy}_3\text{NiGe}_2$  (10) compound from X-ray powder diffraction ( $\text{La}_3\text{NiGe}_2$ -type structure,  $a=1.1272$ ,  $b=0.4207$ ,  $c=1.1218$ ). The proper amounts of starting components were arc melted and annealed at 870 K.

The crystal structure of two ternary compounds  $\text{DyNiGe}_2$  (6) and  $\text{Dy}_{4.75}\text{NiGe}_{4.25}$  (9) has not been evaluated yet (Koterlyn et al. 1988).

#### 4.11.6. Dy–Cu–Ge

No isothermal section is available for the Dy–Cu–Ge system; four ternary compounds have been found and analyzed by various groups of authors.

Rieger and Parthé (1969a) investigated the occurrence of the  $\text{AlB}_2$ -type structure by means of X-ray powder diffraction of arc melted alloys. The data presented were  $\text{DyCu}_{1-0.67}\text{Ge}_{1-1.33}$  with  $a=0.4221$ – $0.4038$ ,  $c=0.3664$ – $0.3637$ . At variance with these data, Iandelli (1993) observed  $\text{DyCuGe}$  with the  $\text{CaIn}_2$ -type ( $a=0.4239$ ,  $c=0.7239$ , X-ray powder analysis). The alloy was obtained from turnings or powders of metals (Dy 99.7 mass%, Cu and Ge 99.99 mass%), which were mixed and sealed in a tantalum crucible under argon, melted by induction heating and annealed for 10 days at 1023 K.

$\text{Dy}_6\text{Cu}_8\text{Ge}_8$  crystallizes with the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$  type, lattice parameters  $a=1.3845$ ,  $b=0.6618$ ,  $c=0.4173$  (Rieger 1970).

Konyk et al. (1988) investigated the crystal structure of  $\text{Dy}_2\text{CuGe}_6$  alloy synthesized by arc melting under argon and annealing at 870 K in an evacuated quartz tube for 720 h. From X-ray powder analysis a  $\text{Ce}_2\text{CuGe}_6$ -type structure was claimed for this phase,  $a = 0.3993$ ,  $b = 0.4100$ ,  $c = 2.0939$ .

Rieger and Parthé (1969b) observed  $\text{DyCu}_2\text{Ge}_2$  with the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a = 0.4029$ ,  $c = 1.0281$ .

Francois et al. (1990) observed the  $\text{CeNiSi}_2$  type for the  $\text{DyCu}_{0.38}\text{Ge}_2$  compound and reported lattice parameters  $a = 0.4092$ ,  $b = 1.635$ ,  $c = 0.3968$  (X-ray powder diffraction) from a sample obtained by the powder metallurgical reaction at 1173 K.

#### 4.11.7. *Dy–Nb–Ge*

A phase diagram for the Dy–Nb–Ge system has not been established. However, the existence of a compound  $\text{Dy}_2\text{Nb}_3\text{Ge}_4$  with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$ -type ( $a = 0.6975$ ,  $b = 1.3510$ ,  $c = 0.7154$ ) was reported by Le Bihan et al. (1996a) from X-ray powder diffraction analysis of arc melted alloy. The starting materials were: Dy and Nb 99.99 mass%, Ge 99.999 mass%.

#### 4.11.8. *Dy–Mo–Ge*

The existence of the  $\text{Dy}_2\text{Mo}_3\text{Ge}_4$  compound with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$  type ( $a = 0.6892$ ,  $b = 1.3112$ ,  $c = 0.7038$ ) was reported by Le Bihan et al. (1996b). For the sample preparation and purity of starting materials, see Dy–Nb–Ge.

#### 4.11.9. *Dy–Ru(Rh, Pd)–Ge*

The ternary Dy–Ru(Rh, Pd)–Ge systems have been studied only with respect to the formation of compounds with specific composition and structure. Their crystallographic characteristics are listed in table 27.

#### 4.11.10. *Dy–Ag–Ge*

No ternary phase diagram has been established for the Dy–Ag–Ge system, however one ternary compound has been characterized.

The crystal structure of the  $\text{DyAgGe}$  compound was firstly investigated by Zanicchi et al. (1983) using X-ray powder diffraction. It was found to adopt the  $\text{ZrNiAl}$  type with lattice parameters  $a = 0.7105$ ,  $c = 0.4198$ . Gibson et al. (1996) reported the single-crystal investigation of this compound. The crystal structure was confirmed and lattice parameters were obtained as  $a = 0.71056$ ,  $c = 0.41960$ . The single crystal was extracted from an arc melted sample annealed at 970 K for ten days.

#### 4.11.11. *Dy–Os(Ir, Pt)–Ge*

No systematic studies have been performed for the ternary Dy–Os(Ir, Pt)–Ge systems. Interaction of dysprosium with osmium (irridium, platinum) and germanium has been studied only with respect to the formation of compounds with a specific composition and structure. The crystallographic characteristics are listed in table 28.

#### 4.11.12. *Dy–Au–Ge*

No ternary phase diagram exists for the Dy–Au–Ge system, however, a ternary compound of dysprosium with gold and germanium in the stoichiometric ratio 1:1:1 has been identified and studied by means of X-ray and metallographic analyses by Rossi et al. (1992). DyAuGe was found to adopt the LiGaGe type with lattice parameters  $a=0.4411$ ,  $c=0.7287$ . The sample was prepared by melting the metals (around 99.9 mass% for dysprosium and 99.99 mass% for gold and germanium) in an induction furnace and annealing at 1070 K for one week.

#### 4.12. *Ho–d element–Ge systems*

##### 4.12.1. *Ho–Cr–Ge*

Brabers et al. (1994) reported the existence of the compound  $\text{HoCr}_6\text{Ge}_6$  with the  $\text{HfFe}_6\text{Ge}_6$  type structure ( $a=0.5158$ ,  $c=0.8269$ ; X-ray powder diffraction). The sample was prepared by arc melting and subsequent annealing at 1073 K for three weeks in a vacuum.

##### 4.12.2. *Ho–Mn–Ge*

No phase diagram is available for the ternary Ho–Mn–Ge system; however three ternary compounds have been observed and characterized by different authors.

Venturini et al. (1992) reported the existence of the compound  $\text{HoMn}_6\text{Ge}_6$  with the  $\text{HfFe}_6\text{Ge}_6$  type ( $a=0.5230$ ,  $c=0.8155$ ; X-ray powder diffraction). The sample was synthesized from a mixture of stoichiometric amounts of the elements, which was compacted and sealed in a silica tube under argon followed by annealing at 1073 K for two weeks.

Rossi et al. (1978b) reported an investigation of the crystal structure of the  $\text{HoMn}_2\text{Ge}_2$  compound ( $\text{CeGa}_2\text{Al}_2$  type,  $a=0.3977$ ,  $c=1.0845$ ; X-ray powder method). The alloy was obtained by melting under argon in an induction furnace and was annealed at 770 K for one week. The metals used were of purity greater than 99.9 mass% for Ho, and greater than 99.99 mass% for Mn and Ge.

$\text{HoMn}_{0.25}\text{Ge}_2$  was found to adopt the  $\text{CeNiSi}_2$  type structure with lattice parameters  $a=0.4097$ ,  $b=1.574$ ,  $c=0.3983$  by Francois et al. (1990) (X-ray powder diffraction data). For sample preparation see  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$  under Gd–Fe–Ge.

##### 4.12.3. *Ho–Fe–Ge*

The phase diagram for the Ho–Fe–Ge system was investigated by Salamakha et al. (1996g) by means of X-ray analysis (fig. 93). Alloys for investigation were prepared by arc melting proper amounts of the constituent elements. The starting materials were used in the form of ingots of holmium (99.9 mass%), iron (99.99 mass%) and germanium (99.999 mass%). The samples were annealed at 870 K for two weeks. Six ternary compounds have been observed and characterized.

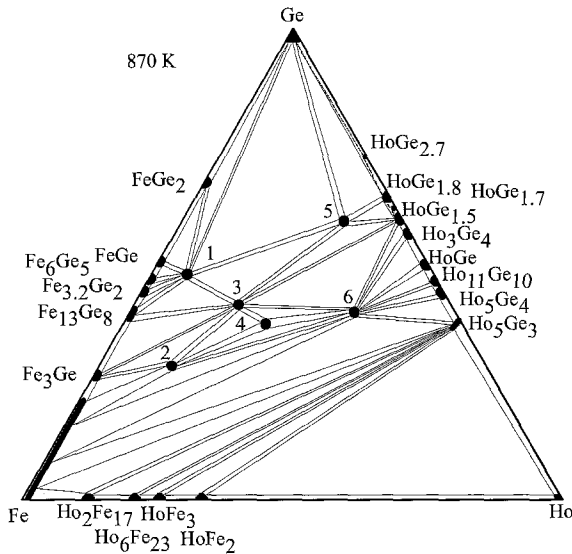

Fig. 93. Ho–Fe–Ge, isothermal section at 870 K.

$\text{HoFe}_6\text{Ge}_6$  (1) was reported to be isotypic with  $\text{YCo}_6\text{Ge}_6$ , lattice parameters  $a=0.5110$ ,  $c=0.4056$  (Mruz et al. 1984). The sample was prepared by arc melting the proper amounts of the starting components, followed by annealing at 870 K for two weeks and finally quenching in cold water. At variance with these data,  $\text{HoFe}_6\text{Ge}_6$  was found to crystallize with the  $\text{TbFe}_6\text{Sn}_6$  type,  $a=0.8111$ ,  $b=1.766$ ,  $c=0.5116$  by Venturini et al. (1992) from X-ray powder diffraction data. The alloy was obtained by powder metallurgical reaction in an evacuated silica tube at 1173 K for two weeks. This suggests that  $\text{HoFe}_6\text{Ge}_6$  may be polymorphic.

Pecharsky et al. (1989) reported  $\text{HoFe}_{0.33}\text{Ge}_2$  (5) to crystallize with the  $\text{CeNiSi}_2$ -type ( $a=0.4102$ ,  $b=1.5689$ ,  $c=0.3986$ ; X-ray powder analysis). The alloy was arc melted and annealed at 870 K. The purity of the starting materials was greater than 99.9 mass%. Francois et al. (1990) confirmed the occurrence of  $\text{CeNiSi}_2$  type for holmium–iron–germanium combinations from the alloys annealed at 1173 K ( $\text{HoFe}_{0.38}\text{Ge}_2$ ;  $a=0.4105$ ,  $b=1.572$ ,  $c=0.3999$ ).

Salamakha et al. (1996g) investigated the crystal structure of  $\text{Ho}_{117}\text{Fe}_{52}\text{Ge}_{112}$  (6) by X-ray powder diffraction ( $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$  type,  $a=2.8238$ ). The alloy was synthesized by arc melting and annealing at 870 K for two weeks. The starting materials were Ho 99.9 mass%, Fe 99.9 mass%, and Ge 99.99 mass%.

According to X-ray powder diffraction data,  $\text{HoFe}_2\text{Ge}_2$  (3) was found to be isostructural with the  $\text{CeGa}_2\text{Al}_2$  type, with lattice parameters  $a=0.3949$ ,  $c=1.0430$  (Rossi et al. 1978a).

Fedyna (1988) reported on the X-ray powder investigation of the crystal structure of  $\text{HoFe}_4\text{Ge}_2$  (2) ( $\text{ZrFe}_4\text{Si}_2$  type,  $a=0.7255$ ,  $c=0.3852$ ) from an arc melted alloy annealed at 870 K alloy.

$\text{Ho}_6\text{Fe}_8\text{Ge}_8$  (4) belongs to the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$  type,  $a = 1.3450$ ,  $b = 0.6781$ ,  $c = 0.4117$ , after Fedyna et al. (1994).

#### 4.12.4. Ho–Co–Ge

The isothermal section of the Ho–Co–Ge system at 870 K over the whole concentration region was derived by Aslan (1990) (fig. 94) employing X-ray and microstructural analyses of 212 alloys which were prepared by arc melting the proper amounts of the constituent elements of high purity. The melted buttons were then annealed in evacuated silica tubes at 870 K for 720 hours.

The ternary phase diagram is characterized by the existence of eleven ternary compounds and by the formation of solid solutions based at the  $\text{Ho}_2\text{Co}_{17}$  and  $\text{HoCo}_5$  binary compounds where the maximum solubility of germanium is 10 at.%. The  $\text{Ho}_5\text{Ge}_3$  phase dissolves 8 at.% Co.

Méot-Meyer et al. (1985a) reported the crystal structure of  $\text{HoCo}_x\text{Ge}_2$  (8),  $x = 0.48$  (CeNiSi<sub>2</sub> type,  $a = 0.4094$ ,  $b = 1.595$ ,  $c = 0.4009$ ). The sample was prepared by powder metallurgical reaction and annealed in an evacuated silica tube at 1173 K. Pecharsky et al. (1989) confirmed the formation and crystal structure of the  $\text{HoCo}_{1-x}\text{Ge}_2$  compound and additionally observed the existence of a homogeneity field from arc melted alloys annealed at 870 K ( $a = 0.4080\text{--}0.4093$ ,  $b = 1.583\text{--}1.592$ ,  $c = 0.3953\text{--}0.4008$ ; X-ray powder analysis).

The crystal structure of  $\text{Ho}_3\text{Co}_4\text{Ge}_{13}$  (3) ( $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a = 0.8735$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample which was prepared by heating a compacted mixture of the starting materials (Ho in pieces, 99.9 mass%; Co and Ge in powder, 99.99 mass%) in an evacuated quartz tube at 1073 K. Bodak et al.

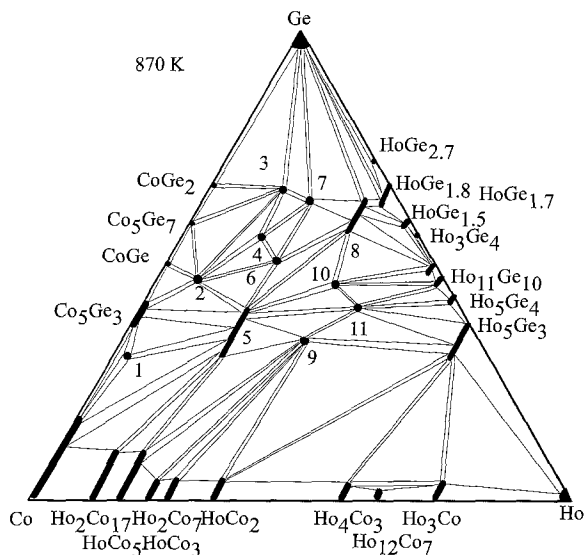

Fig. 94. Ho–Co–Ge, isothermal section at 870 K.

(1987) reported the  $Y_3Co_4Ge_{13}$ -type for the  $Ho_3Co_4Ge_{13}$  compound ( $a=0.8742$ ; X-ray powder data) from arc melted alloy annealed at 870 K.

$HoCo_2Ge_2$  (5) was found to adopt the  $CeGa_2Al_2$  type,  $a=0.3957$ ,  $c=1.0077$  (Szytuła et al. 1980; X-ray powder diffraction). Aslan (1990) confirmed the crystal structure and observed the existence of a homogeneity field for  $HoCo_{2.0+x}Ge_{2-x}$  ( $x=0.5$ ).

From an X-ray powder analysis of alloy annealed at 1173 K,  $Ho_2Co_3Ge_5$  (6) was reported to adopt the  $Lu_2Co_3Si_5$ -type structure,  $a=0.9618$ ,  $b=1.1805$ ,  $c=0.5691$ ,  $\beta=91.9^\circ$  (Venturini et al. 1986b).

The crystal structure of the  $HoCo_6Ge_6$  (2) compound was reported by Buchholz and Schuster (1981) ( $YCo_6Ge_6$  structure type,  $a=0.5074$ ,  $c=0.3910$ ). The sample was melted under argon in a corundum crucible at 1073–1273 K.

Gorelenko et al. (1984) reported the crystal structure of  $HoCoGe$  (9) (TiNiSi type,  $a=0.6851$ ,  $b=0.4198$ ,  $c=0.7253$ ; X-ray powder analysis). The alloy was arc melted, and annealed in an evacuated quartz tube at 870 K for 350 hours.

$Ho_3Co_2Ge_4$  (10) crystallizes with a  $Tb_3Co_2Ge_4$ -type of structure,  $a=1.0523$ ,  $b=0.7958$ ,  $c=0.4152$ ,  $\gamma=107.36^\circ$  (X-ray powder data; Mruz et al. 1989). The sample was prepared by arc melting and annealing at 873 K for 240 h.

$Ho_2CoGe_6$  (7) is isotypic with  $Ce_2CuGe_6$ ,  $a=0.3923$ ,  $b=0.3974$ ,  $c=2.131$  (Oleksyn et al. 1991; X-ray powder diffraction data). The sample was melted in an arc furnace and annealed at 1070 K in an evacuated quartz capsule for 400 h. The purity of the starting materials was greater than 99.9 mass%.

Bodak et al. (1986) reported on the X-ray powder investigation of the compound  $Ho_2CoGe_2$  (11),  $Sc_2CoSi_2$  type,  $a=1.0408$ ,  $b=1.0109$ ,  $c=0.4166$ ,  $\gamma=117.45^\circ$ .

Investigating the isothermal section, Aslan (1990) observed two compounds with unknown structures:  $\sim Ho_3Co_{65}Ge_{32}$  (1) and  $\sim HoCo_2Ge_5$  (4).

#### 4.12.5. Ho–Ni–Ge

Figure 95 represents the isothermal section of the Ho–Ni–Ge phase diagram at 870 K, which was studied by Aslan (1990). The isothermal section was constructed by means of X-ray powder and partly microstructural analyses of 158 alloys which were arc melted, subsequently annealed in evacuated silica tubes for 720 h at 870 K, and finally quenched in cold water. The starting materials were Ho 99.9 mass%, Ni 99.98 mass%, and Ge 99.99 mass%.

The ternary phase diagram is characterized by the existence of ten ternary compounds and by the formation of substitutional solid solutions originating at  $Ho_2Ni_{17}$  and  $HoNi_5$  binary compounds where the maximum solubility of germanium is 17 at.%. The binary  $HoGe_{1.5}$  compound dissolves 15 at.% Ni.

$HoNi_5Ge_3$  (1) was reported to crystallize with the  $YNi_5Si_3$  type,  $a=1.9050$ ,  $b=0.3856$ ,  $c=0.6785$ , by Fedyna et al. (1987). The arc melted alloy, annealed at 870 K, was investigated by X-ray powder diffraction analysis. The starting materials were Ho 99.9 mass%, Ni 99.99 mass%, and Ge 99.999 mass%.

Fig. 95. Ho–Ni–Ge, isothermal section at 870 K.

$\text{Ho}_3\text{Ni}_{11}\text{Ge}_4$  (2) belongs to the  $\text{Sc}_3\text{Ni}_{11}\text{Si}_4$  type,  $a=0.8292$ ,  $c=0.8682$ , after Fedyna et al. (1987). An alloy was prepared in the same manner as  $\text{HoNi}_5\text{Ge}_3$ .

The  $\text{HoNi}_2\text{Ge}_2$  (4) compound was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4021$ ,  $c=0.9757$  (Rieger and Parthé 1969b).

$\text{HoNiGe}_3$  (5) with the  $\text{SmNiGe}_3$ -type structure ( $a=2.1476$ ,  $b=0.4063$ ,  $c=0.4054$ , X-ray powder diffraction analysis) was reported by Bodak et al. (1985). For the details of sample preparation and purity of starting materials, see  $\text{HoNi}_5\text{Ge}_3$ , above.

$\text{Ho}_2\text{NiGe}_6$  (6) has been found by Oleksyn (1990) from X-ray powder diffraction to be isostructural with  $\text{Ce}_2\text{CuGe}_6$  ( $a=0.3941$ ,  $b=2.1108$ ,  $c=0.3991$ ). The sample was prepared by arc melting ingots of the constituting elements and annealing at 1070 K for 700 h. For the purity of starting materials, see  $\text{HoNi}_5\text{Ge}_3$ , above.

Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{HoNi}_{1-x}\text{Ge}_2$  (8) compound by X-ray powder analysis of arc melted alloy annealed at 870 K ( $\text{CeNiSi}_2$  type,  $a=0.4059\text{--}0.4079$ ,  $b=1.5809\text{--}1.5796$ ,  $c=0.3934\text{--}0.3952$ ). Francois et al. (1990) confirmed the structure and reported the composition and lattice parameters  $\text{HoNi}_{0.71}\text{Ge}_2$ ,  $a=0.4084$ ,  $b=1.629$ ,  $c=0.4091$  (X-ray powder diffraction) from a sample obtained by powder metallurgical reaction at 1173 K.

Gorelenko et al. (1984) reported the crystal structure of  $\text{HoNiGe}$  (9) ( $\text{TiNiSi}$  type,  $a=0.6856$ ,  $b=0.4204$ ,  $c=0.7256$ ; X-ray powder analysis). For the experimental details, see  $\text{HoCoGe}$  under Ho–Co–Ge.

The crystal structure of  $\text{HoNiGe}_2$  (7) was reported by Oleksyn (1990):  $\text{NdIrGe}_2$  type,  $a=0.4136$ ,  $b=0.8430$ ,  $c=1.5792$  (X-ray powder diffraction). The sample was prepared by arc melting ingots of the constituting elements and annealing at 1070 K for 700 h.

Bodak et al. (1982) reported on the crystal structure of  $\text{Ho}_3\text{NiGe}_2$  from X-ray powder diffraction ( $\text{La}_3\text{NiGe}_2$  type,  $a = 1.1195$ ,  $b = 0.4197$ ,  $c = 1.1192$ ). This compound, however, apparently does not exist at 870 K.

The crystal structures of two more ternary compounds  $\sim\text{HoNi}_3\text{Ge}_2$  (3) and  $\sim\text{Ho}_4\text{NiGe}_4$  (10) have not yet been evaluated (Aslan 1990).

#### 4.12.6. *Ho–Cu–Ge*

No phase diagram is available for the Ho–Cu–Ge system; however the crystal structures for five ternary compounds are reported by different groups of authors.

Rieger and Parthé (1969a) investigated the occurrence of the  $\text{AlB}_2$ -type structure by means of X-ray powder diffraction of arc melted alloys. The data presented are  $\text{HoCu}_{1-0.67}\text{Ge}_{1-1.33}$  with  $a = 0.4225\text{--}0.400$ ,  $c = 0.3608\text{--}0.402$ . At variance with these data, Iandelli (1993) observed  $\text{HoCuGe}$  with the  $\text{CaIn}_2$ -type structure ( $a = 0.4232$ ,  $c = 0.7188$ , X-ray powder analysis). The alloy was prepared from filings or powders of metals (Ho 99.7 mass%, Cu and Ge 99.99 mass%), which were mixed and sealed in a tantalum crucible under argon, melted by induction heating, and annealed for 10 days at 1023 K.

$\text{Ho}_6\text{Cu}_8\text{Ge}_8$  crystallizes with the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$  type, lattice parameters  $a = 1.384$ ,  $b = 0.662$ ,  $c = 0.417$  (Hanel and Nowotny 1970).

Konyk et al. (1988) investigated the crystal structure of  $\text{Ho}_2\text{CuGe}_6$  alloy prepared by arc melting under argon and annealing at 870 K in an evacuated quartz tube for 720 h. From X-ray powder analysis a  $\text{Ce}_2\text{CuGe}_6$ -type was claimed,  $a = 0.4011$ ,  $b = 0.4129$ ,  $c = 2.1104$ .

Rieger and Parthé (1969b) prepared  $\text{HoCu}_2\text{Ge}_2$  with the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a = 0.4016$ ,  $c = 1.0302$ .

Francois et al. (1990) observed the  $\text{CeNiSi}_2$  type structure for the  $\text{HoCu}_{0.33}\text{Ge}_2$  compound and reported lattice parameters  $a = 0.4074$ ,  $b = 1.618$ ,  $c = 0.3950$  (X-ray powder diffraction) from a sample obtained by powder metallurgical reaction at 1173 K.

#### 4.12.7. *Ho–Nb–Ge*

The phase diagram of the Ho–Nb–Ge system has not been established, but at least one ternary phase is known. The existence of the compound  $\text{Ho}_2\text{Nb}_3\text{Ge}_5$  with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$ -type structure ( $a = 0.6956$ ,  $b = 1.3479$ ,  $c = 0.7131$ ) was reported by Le Bihan et al. (1996a) from X-ray powder diffraction data of an arc melted alloy. The starting materials were: Ho and Nb 99.99 mass%, Ge 99.999 mass%.

#### 4.12.8. *Ho–Mo–Ge*

No phase diagram is available for the Ho–Mo–Ge system, and only one compound was observed and investigated.  $\text{Ho}_2\text{Mo}_3\text{Ge}_4$  was reported to crystallize with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$ -type structure ( $a = 0.6868$ ,  $b = 1.3079$ ,  $c = 0.7032$ ) by Le Bihan et al. (1996b) from X-ray powder diffraction of an arc melted alloy. The starting materials were: Ho and Mo 99.99 mass%, Ge 99.999 mass%.

Fig. 96. Ho–Ru–Ge, isothermal section at 870 K.

#### 4.12.9. Ho–Ru–Ge

The isothermal section for Ho–Ru–Ge was constructed by Sologub (1995) at 870 K by means of X-ray diffraction (fig. 96). The samples were prepared by direct arc melting of pieces of high purity components (greater than 99.9 mass%), annealed at 870 K for two weeks in evacuated quartz ampoules and quenched in cold water. The phase-field distribution is characterized by the formation of seven compounds.

Early investigations of the  $\text{HoRu}_2\text{Ge}_2$  (2) compound showed that it had the  $\text{CeGa}_2\text{Al}_2$ -type structure with  $a=0.4211$ ,  $c=0.9790$  (Francois et al. 1985) from X-ray powder analysis of an alloy obtained by powder metallurgical reaction at 1273 K. The starting components were Ho (3N), Ru (4N), and Ge (4N). Sologub et al. (1995b) confirmed the crystal structure and obtained the lattice parameters  $a=0.4218$ ,  $c=0.9805$ .

Venturini et al. (1986b) reported the structure for the  $\text{Ho}_2\text{Ru}_3\text{Ge}_5$  (3) compound, which crystallizes with the  $\text{U}_2\text{Co}_3\text{Si}_5$ -type of structure. The lattice parameters were reported as  $a=0.9771$ ,  $b=1.241$ ,  $c=0.5706$  (X-ray powder diffraction data). For sample preparation, see  $\text{La}_2\text{Ru}_3\text{Ge}_5$  under La–Ru–Ge.

The  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type structure was announced for the  $\text{Ho}_3\text{Ru}_4\text{Ge}_{13}$  (1) compound ( $a=0.8945$ ) by Segre et al. (1981a) from an X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Ho (3N), Ru (3N), and Ge (6N).

Francois et al. (1990) reported the crystal structure of  $\text{HoRu}_{0.27}\text{Ge}_2$  (4) ( $\text{CeNiSi}_2$  type,  $a=0.4116$ ,  $b=1.577$ ,  $c=0.4007$ ). For sample preparation, see  $\text{GdFeGe}_2$  under Gd–Fe–Ge. Sologub et al. (1995b) confirmed the formation and crystal structure for this compound,  $a=0.4105$ ,  $b=1.5701$ ,  $c=0.4008$  (X-ray powder diffraction).

Sologub et al. (1994a) reported on a single-crystal investigation of two compounds: HoRuGe (5), TiNiSi type,  $a=0.6980$ ,  $b=0.4351$ ,  $c=0.7281$ , and  $\text{Ho}_3\text{Ru}_2\text{Ge}_3$  (6),  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  type,  $a=0.4242$ ,  $b=1.0731$ ,  $c=1.3840$ . The single crystals were obtained from samples which were arc melted and annealed at 870 K for 400 h.

$\text{Ho}_2\text{RuGe}_2$  (7) was found to crystallize with the  $\text{Sc}_2\text{CoSi}_2$ -type structure,  $a=1.0643$ ,  $b=0.4259$ ,  $c=1.0203$ ,  $\beta=118.0^\circ$  by Sologub et al. (1995b).

#### 4.12.10. Ho–Rh–Ge

The phase relations in the ternary Ho–Rh–Ge system (0–50 at.% Rh) at 870 K were investigated by Sologub (1995) (fig. 97). Fourteen ternary compounds were found to exist within the concentration region investigated. For experimental procedures, see Ho–Ru–Ge.

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{Ho}_3\text{Rh}_4\text{Ge}_{13}$  (1) compound from a sample prepared by heating a mixture of starting components (Ho 3N, Rh 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to be of the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8916$ .

Francois et al. (1985) determined the  $\text{CeGa}_2\text{Al}_2$ -type structure for the  $\text{HoRh}_2\text{Ge}_2$  (3) compound,  $a=0.4101$ ,  $c=1.0196$ .

$\text{Ho}_2\text{Rh}_3\text{Ge}_5$  (4) was found to crystallize with  $\text{Lu}_2\text{Co}_3\text{Si}_5$ -type structure ( $a=1.1353$ ,  $b=1.1976$ ,  $c=0.5813$ ,  $\beta=119.05^\circ$ ; X-ray single-crystal data) by Venturini et al. (1986b) from a sample synthesized by powder metallurgical reaction at 1173 K. The purity of the starting materials was greater than 99.9 mass%.

Hovestreydt et al. (1982) reported the crystal structure of the  $\text{HoRhGe}$  (8) compound (TiNiSi type,  $a=0.6964$ ,  $b=0.4272$ ,  $c=0.7516$ ; X-ray powder data) from an arc melted

Fig. 97. Ho–Rh–Ge, partial isothermal section at 870 K (0–50 at.% Rh).

sample annealed at 1270 K for 1–2 weeks. The starting components were Ho (3N), Rh (4N), and Ge (5N).

Salamakha and Sologub (1999) reported on the crystal structure of the  $\text{Ho}_3\text{Rh}_2\text{Ge}_2$  (13) compound ( $\text{La}_3\text{Ni}_2\text{Ga}_2$  type,  $a=0.55367$ ,  $b=0.7726$ ,  $c=1.3165$ ; X-ray powder diffraction data). For the details of sample preparation, see  $\text{La}_3\text{Rh}_2\text{Ge}_2$  under La–Rh–Ge.

Sologub (1995) established the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type for the  $\text{Ho}_4\text{Rh}_{13}\text{Ge}_9$  (2) compound,  $a=0.3962$ ,  $b=1.1034$ ,  $c=1.9203$ . For sample preparation, see Ho–Ru–Ge.

Venturini et al. (1984) observed the existence of the  $\text{Ho}_5\text{Rh}_4\text{Ge}_{10}$  (6) compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$  type ( $a=1.2902$ ,  $c=0.4242$ ; X-ray powder diffraction) from a sample obtained by heating amixture of powders in an evacuated tube at 1073 K. Salamakha and Sologub (1999) confirmed the  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type of structure by a single-crystal method,  $a=1.29336$ ,  $c=0.42596$ . The single crystal was taken from an arc melted sample annealed at 870 K.

$\text{Ho}_4\text{Rh}_7\text{Ge}_6$  (5) was reported to adopt the  $\text{U}_4\text{Re}_7\text{Si}_6$  type structure,  $a=0.8305$  (Francois et al. 1985) from a sample which was obtained by heating a mixture of powders of the starting materials (Ho 3N, Rh 4N, Ge 4N) in evacuated quartz tubes at 1273 K.

Francois et al. (1990) reported the crystal structure of  $\text{HoRh}_{0.28}\text{Ge}_2$  (7) ( $\text{CeNiSi}_2$  type,  $a=0.4107$ ,  $b=1.584$ ,  $c=0.3988$ ). For sample preparation, see GdFeGe<sub>2</sub> under Gd–Fe–Ge.

Four more ternary compounds were observed and investigated by Sologub (1995) using an X-ray single-crystal method:  $\text{Ho}_3\text{Rh}_2\text{Ge}_3$  (9),  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  type,  $a=0.425$ ,  $b=1.026$ ,  $c=1.488$ ;  $\sim\text{Ho}_{3+x}\text{Rh}_2\text{Ge}_{3+x}$  (10), orthorhomb.,  $a=0.423$ ,  $b=1.024$ ,  $c=10.2$ ;  $\text{Ho}_2\text{RhGe}_2$  (11),  $\text{Sc}_2\text{CoSi}_2$  type,  $a=1.0465$ ,  $b=0.42670$ ,  $c=1.02203$ ,  $\beta=117.2^\circ$ ;  $\sim\text{Ho}_{2+x}\text{RhGe}_{2+x}$  (12), monoclinic,  $a=1.042$ ,  $b=0.428$ ,  $c=6.3$ ,  $\beta=117^\circ$ .

The crystal structure of  $\sim\text{Ho}_5\text{Rh}_3\text{Ge}_2$  (14) has not been evaluated (Sologub 1995).

#### 4.12.11. Ho–Pd–Ge

A systematic study of the Ho–Pd–Ge system at 870 K was performed by Sologub (1995) over the whole concentration region by means of X-ray powder analysis (fig. 98). The samples were prepared by arc melting under an argon atmosphere and annealed in evacuated quartz ampoules at 870 K for 500 hours. The starting materials were 99.8 mass% pure or better.

Phase relations are characterized by the existence of ten ternary compounds and by the formation of an extended solid solution originating at the  $\text{HoPd}_3$  binary compound. The maximum solubility of Ge in  $\text{HoPd}_3$  was observed as 12 at.%. The solubility of the third component in other binary compounds was found to be negligible.

The existence of the  $\text{HoPd}_2\text{Ge}_2$  (2) compound ( $\text{CeGa}_2\text{Al}_2$  type,  $a=0.4220$ ,  $c=1.0018$ ) was reported by Bodak and Sologub (1991a). The sample was prepared in the same manner as the Ho–Pd–Ge alloys.

Bodak and Sologub (1991a) reported on the X-ray powder analysis of the  $\text{Ho}_2\text{PdGe}_6$  (3) compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$  type,  $a=0.4080$ ,  $b=0.4007$ ,  $c=2.140$ . For the experimental procedure, see Ho–Pd–Ge.

Fig. 98. Ho-Pd-Ge, isothermal section at 870 K.

The crystal structure of the compound  $\text{HoPd}_2\text{Ge}$  (4) was found to be of the  $\text{YPd}_2\text{Si}$  type ( $a=0.7318$ ,  $b=0.6036$ ,  $c=0.5553$ ; X-ray powder diffraction) by Jorda et al. (1983). For the experimental procedure, see  $\text{LaPd}_2\text{Ge}$  under La-Pd-Ge. The starting materials were Pd 99.99 mass%, Ge specpure quality, and Ho 99.9 mass%. Sologub (1995) confirmed the structure of  $\text{HoPd}_2\text{Ge}$  and reported similar lattice parameters ( $a=0.7321$ ,  $b=0.6045$ ,  $c=0.5563$ ; X-ray powder diffraction).

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound  $\text{HoPdGe}$  (8) adopts the  $\text{KHg}_2$ -type of structure,  $a=0.4360$ ,  $b=0.6938$ ,  $c=0.7547$ . For sample preparation, see  $\text{LaPdGe}$  under La-Pd-Ge. The starting materials were Ho (3N), Pd (4N), and Ge (5N). Sologub (1995) reported a single-crystal investigation of  $\text{HoPdGe}$  from an arc melted specimen annealed at 870 K for 500 h ( $\text{KHg}_2$  type,  $a=0.4358$ ,  $b=0.6922$ ,  $c=0.7546$ ).

Francois et al. (1990) investigated the crystal structure of the  $\text{HoPd}_{0.33}\text{Ge}_2$  (7) compound ( $\text{CeNiSi}_2$  type,  $a=0.4118$ ,  $b=1.593$ ,  $c=0.4002$ ). In the course of studying the phase equilibria in the Ho-Pd-Ge system at 870 K, Sologub (1995) confirmed the existence of the compound with the  $\text{CeNiSi}_2$  type structure and obtained similar lattice parameters:  $a=0.4107$ ,  $b=1.5924$ ,  $c=0.3979$ .

Sologub (1995) studied the crystal structures of  $\text{HoPdGe}_2$  (5) ( $\text{NdIrGe}_2$  type,  $a=0.4234$ ,  $b=1.597$ ,  $c=0.8715$ ) and  $\text{HoPd}_{0.8-0.6}\text{Ge}_{1.2-1.4}$  (9) ( $\text{AlB}_2$  type,  $a=0.4237-0.4276$ ,  $c=0.3828-0.3721$ ) by X-ray powder diffraction. The experimental details are given above (Ho-Pd-Ge isothermal section).

$\text{Ho}_6\text{Pd}_8\text{Ge}_8$  (6) was found to crystallize with the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$ -type structure,  $a=0.42348$ ,  $b=0.68373$ ,  $c=1.4093$  (Gladyshevsky et al. 1991b; X-ray single-crystal data).

Sologub et al. (1994b) investigated  $\text{Ho}_{26}\text{Pd}_4(\text{Pd}, \text{Ge})_{19-x}$  (10) by an X-ray single-crystal method: own structure type,  $a = 1.4523$ ,  $c = 1.0318$ . The alloy was arc melted and annealed at 870 K for 500 h.

The crystal structure of the  $\sim\text{HoPd}_5\text{Ge}_3$  (1) compound has not yet been established (Sologub 1995).

#### 4.12.12. Ho–Ag–Ge

The isothermal section of the Ho–Ag–Ge system at 870 K was reported by Sologub and Protsyk (1991) from an X-ray powder analysis of 54 alloys (fig. 99). The samples were obtained by arc melting the components in purified argon and annealing at 870 K for 500 h in evacuated quartz tubes. Finally the alloys were water quenched. The purity of the starting components was Ho 99.8 mass%, Ag 99.9 mass%, and Ge 99.999 mass%. One ternary compound was found to exist in this system at 870 K.

Sologub and Protsyk (1991) reported on the crystal structure of the HoAgGe compound. It was found to adopt the ZrNiAl-type structure,  $a = 0.7084$ ,  $c = 0.41793$  (X-ray powder diffraction). Gibson et al. (1996) confirmed the crystal structure from X-ray powder diffraction of an arc melted alloy annealed at 970 K for ten days, and presented the lattice parameters  $a = 0.70783$ ,  $c = 0.41826$ .

Fig. 99. Ho–Ag–Ge, isothermal section at 870 K.

#### 4.12.13. Ho–Re–Ge

The only information on the system Ho–Re–Ge is due to Francois et al. (1990) who investigated the occurrence of the compound with the  $\text{CeNiSi}_2$  type; no phase diagram is available. The  $\text{HoRe}_{0.25}\text{Ge}_2$  compound was found to adopt the  $\text{CeNiSi}_2$ -type structure with lattice parameters  $a = 0.4128$ ,  $b = 1.578$ ,  $c = 0.4028$  by Francois et al. (1990) (X-ray

powder diffraction data). The alloy was prepared from a mixture of the proper amounts of the components with purity 99.9 mass% by metallurgical reaction in a quartz tube at 1173 K.

#### 4.12.14. Ho–Os–Ge

Bodak and Sologub (1991b) were the first to investigate, by X-ray powder diffraction, the phase equilibria within the Ho–Os–Ge system at 870 K over the whole concentration region; samples were prepared as described under Ho–Ru–Ge. The phase relations are characterized by the existence of three ternary compounds (fig. 100).

Bodak et al. (1991) indicated a  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure for  $\text{Ho}_5\text{Os}_4\text{Ge}_{10}$  (2) from X-ray single-crystal diffraction and reported the lattice parameters  $a=1.2984$ ,  $c=0.42820$ .

Fig. 100. Ho–Os–Ge, isothermal section at 870 K.

$\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type structure was announced for the  $\text{Ho}_3\text{Os}_4\text{Ge}_{13}$  compound (1) ( $a=0.8977$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Ho (3N), Os (3N), and Ge (6N). At variance with these data, Bodak and Sologub (1991b) observed the  $\text{Y}_3\text{Co}_4\text{Ge}_{13}$  type for a  $\text{Ho}_3\text{Os}_4\text{Ge}_{13}$  alloy which was arc melted and annealed at 870 K for 500 hours ( $a=0.89737$ ; X-ray powder diffraction).

$\text{Ho}_2\text{OsGe}_2$  (3) was found to adopt the  $\text{Sc}_2\text{CoSi}_2$  type structure,  $a=1.0691$ ,  $b=0.42618$ ,  $c=1.0050$ ,  $\beta=118.07^\circ$  (X-ray single-crystal analyses; Gladyshevsky et al. 1991b).

#### 4.12.15. Ho–Ir–Ge

The partial isothermal section for the Ho–Ir–Ge system at 870 K (0–50 at.% Ir) was established by Sologub (1995) (fig. 101). For sample preparation, see Ho–Ru–Ge. Five

Fig. 101. Ho–Ir–Ge, partial isothermal section at 870 K (0–50 at.% Ir).

ternary compounds were confirmed and eight ternary phases were observed for the first time. No homogeneous ranges were encountered for the ternary compounds.

Venturini et al. (1984) observed the existence of the  $\text{Ho}_5\text{Ir}_4\text{Ge}_{10}$  (5) compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure from X-ray powder diffraction of a sample obtained by heating the starting components in an evacuated tube at 1073 K,  $a = 1.2878$ ,  $c = 0.4286$ .

Venturini et al. (1985b) reported on an X-ray powder diffraction study of the  $\text{Ho}_3\text{Ir}_4\text{Ge}_{13}$  (1) compound from a sample prepared by heating a mixture of the starting components (Ho 3N, Ir 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to adopt the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a = 0.8931$ .

Hovestreydt et al. (1982) reported the crystal structure of the  $\text{HoIrGe}$  (7) compound (TiNiSi type,  $a = 0.6801$ ,  $b = 0.4252$ ,  $c = 0.7595$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. The starting components were Ho (3N), Ir (4N), and Ge (5N).

Francois et al. (1987) reported the crystal structure of  $\text{HoIrGe}_2$  (4) (NdIrGe<sub>2</sub> type,  $a = 0.4244$ ,  $b = 1.595$ ,  $c = 0.8804$ ). The sample was prepared by heating mixtures of powders of the starting components (Ho 3N, Ir 3N, Ge 3N) in an evacuated silica tube at 1173 K.

$\text{HoIr}_{0.28}\text{Ge}_2$  (6) was found to crystallize with a  $\text{CeNiSi}_2$  type,  $a = 0.4108$ ,  $b = 1.585$ ,  $c = 0.3988$  (X-ray powder diffraction; Sologub 1995). For sample preparation, see Ho–Ru–Ge.

$\text{Ho}_4\text{Ir}_7\text{Ge}_6$  (3) was reported to adopt the  $\text{U}_4\text{Re}_7\text{Si}_6$  type ( $a = 0.8311$ ; Francois et al. 1985) from a sample obtained by heating a mixture of powders of the starting materials (Ho 3N, Os 4N, Ge 4N) in an evacuated quartz tube at 1273 K.

Five other ternary compounds were observed and characterized by an X-ray single-crystal method by Sologub et al. (1993) and Sologub (1995):  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$  (2) belongs to a

new structure type,  $a=0.3954$ ,  $b=1.1186$ ,  $c=1.9301$  (Sologub et al. 1993);  $\text{Ho}_3\text{Ir}_2\text{Ge}_3$  (8) adopts  $\text{Hf}_3\text{Ni}_2\text{Si}_3$ -type structure with  $a=0.423$ ,  $b=1.024$ ,  $c=1.485$  (Sologub 1995);  $\sim\text{Ho}_{3+x}\text{Ir}_2\text{Ge}_{3+x}$  (9) is orthorhombic,  $a=0.424$ ,  $b=1.025$ ,  $c=10.25$  (Sologub 1995);  $\text{Ho}_2\text{IrGe}_2$  (10) crystallizes with the  $\text{Sc}_2\text{CoSi}_2$ -type structure,  $a=1.047$ ,  $b=0.428$ ,  $c=1.079$ ,  $\beta=118^\circ$  (Sologub 1995);  $\sim\text{Ho}_{2+x}\text{IrGe}_{2+x}$  (11) is monoclinic,  $a=1.042$ ,  $b=0.428$ ,  $c=6.3$ ,  $\beta=117^\circ$  (Sologub 1995). The alloys for this investigation were prepared in the same manner as Ho–Ru–Ge.

Two more compounds with unknown structures were observed by Sologub (1995):  $\sim\text{Ho}_5\text{Ir}_3\text{Ge}_2$  (12) and  $\sim\text{Ho}_5\text{Ir}_2\text{Ge}_3$  (13).

#### 4.12.16. Ho–Pt–Ge

The phase equilibria in the Ho–Pt–Ge system (fig. 102) have been investigated by Sologub (1995) by means of an X-ray analysis of 90 alloys which were arc melted and subsequently annealed in evacuated silica tubes for 500 h at 870 K and finally quenched in water. The starting materials were Ho 99.8 mass%, Pt 99.99 mass% and Ge 99.999 mass%. One ternary compound was confirmed and ten ternary phases were observed for the first time.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound  $\text{HoPtGe}$  (8) adopts the  $\text{TiNiSi}$ -type structure,  $a=0.6949$ ,  $b=0.4328$ ,  $c=0.7535$ . For sample preparation, see  $\text{LaPdGe}$  under La–Pd–Ge.

Sologub et al. (1995a) reported on the X-ray powder analysis of the  $\text{Ho}_2\text{PtGe}_6$  (3) compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.40441$ ,  $b=0.40026$ ,  $c=2.1571$ . For sample preparation, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge.

X-ray single-crystal analysis was employed to investigate the crystal structure of the

Fig. 102. Ho–Pt–Ge, isothermal section at 870 K.

HoPtGe<sub>2</sub> (6) compound, NdIrGe<sub>2</sub> type,  $a=0.4292$ ,  $b=0.8702$ ,  $c=1.6172$  (Salamakha and Sologub 1998). The single crystal was obtained from an arc melted sample annealed at 870 K for 500 h.

Five more ternary compounds in the Ho–Pt–Ge system at 870 K were observed and characterized by Sologub (1995) in the course of phase equilibrium studies using X-ray powder diffraction: Ho<sub>2</sub>Pt<sub>7</sub>Ge<sub>4</sub> (2), Ce<sub>2</sub>Pt<sub>7</sub>Ge<sub>4</sub>-type structure,  $a=1.984$ ,  $b=0.4062$ ,  $c=1.1427$ ; HoPt<sub>2</sub>Ge (5), YPd<sub>2</sub>Si-type structure,  $a=0.7218$ ,  $b=0.6036$ ,  $c=0.5453$ ; HoPt<sub>0.22</sub>Ge<sub>2</sub> (7), CeNiSi<sub>2</sub>-type structure,  $a=0.4102$ ,  $b=1.592$ ,  $c=0.3951$ ; Ho(Pt,Ge)<sub>2</sub> (10), AlB<sub>2</sub>-type structure,  $a=0.4227$ ,  $c=0.3822$ ; Ho<sub>2</sub>PtGe (11), CrB-type structure,  $a=0.4022$ ,  $b=1.0864$ ,  $c=0.4282$ .

Three ternary compounds with unknown structure types were observed by X-ray powder diffraction at 870 K:  $\sim$ HoPt<sub>5</sub>Ge<sub>3</sub> (1),  $\sim$ Ho<sub>3</sub>Pt<sub>4</sub>Ge<sub>6</sub> (4) and  $\sim$ Ho<sub>3</sub>Pt<sub>2</sub>Ge<sub>4</sub> (9) (Sologub 1995).

#### 4.12.17. Ho–Au–Ge

Information on interaction of holmium with gold and germanium is due to the work of two groups of authors (Sologub 1995 and Rossi et al. 1992). A phase diagram of the Ho–Au–Ge system is not available, however, one ternary compound has been observed and characterized.

A ternary compound of holmium with gold and germanium in the stoichiometric ratio 1:1:1 has been identified and studied by means of X-ray and metallographic analyses by Rossi et al. (1992). HoAuGe was found to adopt the LiGaGe type with lattice parameters  $a=0.4416$ ,  $c=0.7335$ . Samples were prepared by melting the metals in an induction furnace, and annealing the resulting alloys at 1070 K for one week. The metal used had a purity of about 99.9 mass% for holmium and 99.99 mass% for gold and germanium. Sologub (1995) confirmed the structure type from X-ray powder diffraction of an alloy with equiatomic composition which was obtained by arc melting the metals and annealing the resulting button at 870 K for 500 h:  $a=0.44015$ ,  $b=0.7231$ .

#### 4.13. Er–d element–Ge systems

##### 4.13.1. Er–Cr–Ge

Brabers et al. (1994) reported the existence of a compound ErCr<sub>6</sub>Ge<sub>6</sub> with the HfFe<sub>6</sub>Ge<sub>6</sub>-type structure ( $a=0.5150$ ,  $c=0.8258$ ; X-ray powder diffraction). For sample preparation, see TbCr<sub>6</sub>Ge<sub>6</sub> under Tb–Cr–Ge.

##### 4.13.2. Er–Mn–Ge

No systematic study of the Er–Mn–Ge system has been carried out so far; however two ternary compounds were observed and investigated by two groups of authors (Rossi et al. 1978b, Venturini et al. 1992).

ErMn<sub>6</sub>Ge<sub>6</sub> was found to crystallize in the HfFe<sub>6</sub>Ge<sub>6</sub>-type structure by Venturini et al. (1992),  $a=0.5221$ ,  $c=0.8142$  (X-ray powder diffraction data). For sample preparation, see TbMn<sub>6</sub>Ge<sub>6</sub> under Tb–Mn–Ge.

Rossi et al. (1978b) reported an investigation of the crystal structure of the  $\text{ErMn}_2\text{Ge}_2$  compound (CeGa<sub>2</sub>Al<sub>2</sub>-type structure,  $a=0.3963$ ,  $c=1.0835$ ; X-ray powder method). For the experimental details, see  $\text{TbMn}_2\text{Ge}_2$  under Tb–Mn–Ge.

#### 4.13.3. Er–Fe–Ge

The isothermal section of the Er–Fe–Ge system at 1070 K (fig. 103) was investigated by Oleksyn (1990) by means of metallographic, X-ray and microprobe analyses. Alloys for investigation were prepared by arc melting followed by annealing at 1070 K for 350 hours. The purity of the starting components was Er 99.82 mass%, Fe 99.90 mass%, and Ge 99.99 mass%. Eight ternary compounds were found to exist. The solubility of germanium in iron was established as 18 at.%.

$\text{ErFe}_6\text{Ge}_6$  (1) was reported to be isotypic with the crystal structure of  $\text{YCo}_6\text{Ge}_6$  with lattice parameters  $a=0.5100$ ,  $c=0.4041$  by Mruz et al. (1984) (X-ray powder diffraction; for sample preparation, see  $\text{TbFe}_6\text{Ge}_6$  under Tb–Fe–Ge); and  $a=0.51086$ ,  $c=0.4048$  by Oleksyn (1990) (X-ray powder diffraction). At variance with these data, Venturini et al. (1992) reported the  $\text{HoFe}_6\text{Sn}_6$ -type structure for  $\text{ErFe}_6\text{Ge}_6$ ,  $a=0.8103$ ,  $b=2.652$ ,  $c=0.5108$  from X-ray powder diffraction data. The alloy was obtained by powder metallurgical reaction in an evacuated silica tube at 1173 K for two weeks.

Pecharsky et al. (1989) reported  $\text{ErFe}_x\text{Ge}_{2-x}$  (6) to crystallize with the CeNiSi<sub>2</sub>-type structure ( $a=0.4079\text{--}0.4086$ ,  $b=1.5609\text{--}1.5930$ ,  $c=0.3967\text{--}0.3976$ ; X-ray powder analysis). The alloy was arc melted and annealed at 870 K. The purity of the starting materials was greater than 99.9 mass%. Oleksyn (1990) determined the homogeneity region for the  $\text{ErFe}_{0.06\text{--}0.30}\text{Ge}_{1.94\text{--}1.70}$  (CeNiSi<sub>2</sub>-type) compound and obtained lattice parameters  $a=0.4083\text{--}0.4080$ ,  $b=1.5630\text{--}1.5616$ ,  $c=0.3982\text{--}0.3974$ . Francois et al.

Fig. 103. Er–Fe–Ge, isothermal section at 1070 K.

(1990) confirmed the occurrence of the CeNiSi<sub>2</sub>-type structure for erbium-iron-germanium combinations from alloys annealed at 1173 K (ErFe<sub>0.36</sub>Ge<sub>2</sub>;  $a=0.4098$ ,  $b=1.565$ ,  $c=0.3987$ ).

According to X-ray powder diffraction data, ErFe<sub>2</sub>Ge<sub>2</sub> (3) is isostructural with CeGa<sub>2</sub>Al<sub>2</sub>, lattice parameters  $a=0.3945$ ,  $c=1.0435$  (Bara et al. 1990). For the experimental procedure, see TbFe<sub>2</sub>Ge<sub>2</sub> under Tb-Fe-Ge. The crystal structure was also confirmed by Oleksyn (1990) from X-ray powder diffraction,  $a=0.3932$ ,  $c=1.0417$ .

ErFe<sub>4</sub>Ge<sub>2</sub> (2) was observed to adopt the ZrFe<sub>4</sub>Si<sub>2</sub>-type of structure,  $a=0.7229$ ,  $c=0.3842$ , from X-ray powder diffraction of an arc melted sample annealed at 870 K (Fedyna 1988). The crystallographic characteristics obtained by Oleksyn (1990) for ErFe<sub>4</sub>Ge<sub>2</sub> are in good agreement: ZrFe<sub>4</sub>Si<sub>2</sub> type,  $a=0.7246$ ,  $c=0.3864$ .

Four more ternary compounds were observed for the first time and characterized by Oleksyn (1990): Er<sub>6</sub>Fe<sub>8</sub>Ge<sub>8</sub> (4), Gd<sub>6</sub>Cu<sub>8</sub>Ge<sub>8</sub> type,  $a=1.3460$ ,  $b=0.6815$ ,  $c=0.41057$  (X-ray powder diffraction); Er<sub>9</sub>Fe<sub>10</sub>Ge<sub>10</sub> (5), Tm<sub>9</sub>Fe<sub>10</sub>Ge<sub>10</sub> type,  $a=0.5393$ ,  $b=1.3343$ ,  $c=1.3949$  (X-ray single-crystal data); Er<sub>3</sub>Fe<sub>2</sub>Ge<sub>3</sub> (7), Hf<sub>3</sub>Ni<sub>2</sub>Si<sub>3</sub> type,  $a=0.41491$ ,  $b=1.0591$ ,  $c=1.3758$  (X-ray powder diffraction); Er<sub>117</sub>Fe<sub>52</sub>Ge<sub>112</sub> (8), Tb<sub>117</sub>Fe<sub>52</sub>Ge<sub>112</sub> type,  $a=0.2838$  (X-ray powder diffraction).

Two compounds were observed from arc melted samples investigated by Oleksyn (1990) using a single-crystal method: Er<sub>6-x</sub>Fe<sub>6</sub>Ge<sub>4</sub>, new structure type,  $a=0.5086$ ,  $c=0.7851$ , and Er<sub>3</sub>FeGe<sub>3</sub>, W<sub>3</sub>CoB<sub>3</sub> type,  $a=0.4005$ ,  $b=1.0544$ ,  $c=1.4135$ . Apparently these phases are not stable equilibrium phases at 1070 K.

#### 4.13.4. Er-Co-Ge

The isothermal section of the Er-Co-Ge system at 1070 K over the whole concentration region was derived by Oleksyn (1990) (fig. 104) employing X-ray phase and microstructural and microprobe analyses of alloys prepared by arc melting proper amounts of the constituent elements (Er 99.82 mass%, Co 99.90 mass%, Ge 99.99 mass%). The melted buttons were then annealed in evacuated silica tubes at 1070 K for 350 hours. Sixteen ternary compounds were found to exist. Extensive solid solubility regions of Ge in Fe (10 at.%) and in Er<sub>2</sub>Co<sub>17-x</sub> (10 at.%) were observed.

The crystal structure of the ErCo<sub>6</sub>Ge<sub>6</sub> (2) compound was reported by Buchholz and Schuster (1981) (YCo<sub>6</sub>Ge<sub>6</sub> structure type,  $a=0.5074$ ,  $c=0.3910$ ). For experimental details see ErCo<sub>6</sub>Ge<sub>6</sub> under Er-Co-Ge.

Méot-Meyer et al. (1985a) reported the crystal structure of ErCo<sub>x</sub>Ge<sub>2</sub> (13) (CeNiSi<sub>2</sub> type,  $a=0.4078$ ,  $b=1.586$ ,  $c=0.3985$ ). Samples were prepared by powder metallurgical reaction and annealed in an evacuated silica tube at 1173 K. Pecharsky et al. (1989) confirmed the formation and crystal structure of the ErCo<sub>x</sub>Ge<sub>2</sub> compound from arc melted alloys annealed at 870 K ( $a=0.3983-0.4089$ ,  $b=1.5706-1.5805$ ,  $c=0.3955-0.3986$ ; X-ray powder analysis). Oleksyn (1990) established the homogeneity region for the compound with CeNiSi<sub>2</sub> type: ErCo<sub>0.09-0.33</sub>Ge<sub>1.91-1.67</sub>,  $a=0.4058-0.4003$ ,  $b=1.5743-1.5766$ ,  $c=0.3964-0.3932$  (X-ray powder diffraction).

Fig. 104. Er-Co-Ge, isothermal section at 1070 K.

Fedyina (1988) reported the  $\text{ErCo}_4\text{Ge}_2$  (3) compound to have  $\text{ZrFe}_4\text{Si}_2$ -type structure,  $a=0.7217$ ,  $c=0.3743$  (X-ray powder diffraction).

The crystal structure of  $\text{Er}_3\text{Co}_4\text{Ge}_{13}$  (5) ( $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8726$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample which was prepared by heating a compacted mixture of the starting materials (Er in pieces, 99.9 mass%; Co and Ge in powder, 99.99 mass%) in an evacuated quartz tube at 1073 K. Bodak et al. (1987) reported  $\text{Y}_3\text{Co}_4\text{Ge}_{13}$  type for the  $\text{Er}_3\text{Co}_4\text{Ge}_{13}$  compound ( $a=0.8731$ ; X-ray powder data) from arc melted alloy annealed at 870 K.

$\text{ErCo}_2\text{Ge}_2$  (6) was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.3959$ ,  $c=1.0057$  (Oleksyn 1990; X-ray powder diffraction).

From X-ray powder analysis of an alloy annealed at 1173 K,  $\text{Er}_2\text{Co}_3\text{Ge}_5$  (7) was reported to adopt  $\text{Lu}_2\text{Co}_3\text{Si}_5$ -type structure,  $a=0.9601$ ,  $b=1.178$ ,  $c=0.5680$ ,  $\beta=91.9^\circ$  (Venturini et al. 1986b).

Gorelenko et al. (1984) reported the crystal structure of  $\text{ErCoGe}$  (11) (TiNiSi type,  $a=0.6815$ ,  $b=0.4181$ ,  $c=0.7245$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

$\text{Er}_3\text{Co}_2\text{Ge}_4$  (12) crystallizes with the  $\text{Tb}_3\text{Co}_2\text{Ge}_4$ -type structure,  $a=1.0459$ ,  $b=0.7938$ ,  $c=0.4148$ ,  $\gamma=107.20^\circ$  (X-ray powder diffraction; Mruz et al. 1989).

Bodak et al. (1986) reported an X-ray powder investigation of the compound  $\text{Er}_2\text{CoGe}_2$  (15):  $\text{Sc}_2\text{CoSi}_2$  type,  $a=1.0359$ ,  $b=1.0181$ ,  $c=0.4142$ ,  $\gamma=116.89^\circ$ .

$\text{Er}_2\text{CoGe}_6$  is isotypic with  $\text{Ce}_2\text{CuGe}_6$  (9),  $a=0.39777$ ,  $b=0.39331$ ,  $c=2.1386$  (Oleksyn et al. 1991; X-ray powder diffraction data). The sample was melted in an arc furnace and annealed at 1070 K in an evacuated quartz capsule for 400 h. The purity of the starting materials was greater than 99.9 mass%.

$\text{Er}_5\text{Co}_4\text{Ge}_{10}$  (10) was found to adopt the  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure,  $a = 1.2663$ ,  $c = 0.41504$  (Oleksyn 1990; X-ray powder diffraction).

$\text{Er}_3\text{Co}_2\text{Ge}_3$  (14) crystallizes with the  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  type structure,  $a = 0.4145$ ,  $b = 1.0337$ ,  $c = 1.3784$  (Oleksyn 1990; X-ray powder diffraction).

Four compounds with unknown structures were observed by Oleksyn (1990) in the Er–Co–Ge system at 1070 K:  $\sim\text{Er}_{0.03}\text{Co}_{0.65}\text{Ge}_{0.32}$  (1),  $\sim\text{Er}_{0.15}\text{Co}_{0.30}\text{Ge}_{0.55}$  (4),  $\sim\text{Er}_{0.20}\text{Co}_{0.20}\text{Ge}_{0.60}$  (8) and  $\sim\text{Er}_{0.42}\text{Co}_{0.10}\text{Ge}_{0.48}$  (16).

One more compound was observed from an arc melted sample and investigated by Oleksyn (1990) using single-crystal method:  $\text{Er}_{6-x}\text{Co}_6\text{Ge}_4$ , new structure type,  $a = 0.5091$ ,  $c = 0.7861$ .

#### 4.13.5. Er–Ni–Ge

Figure 105 presents the isothermal section of the Er–Ni–Ge phase diagram at 1070 K, studied by Oleksyn (1990). The isothermal section was constructed by means of X-ray powder microprobe and microstructural analyses of 240 alloys which were arc melted, subsequently annealed in evacuated silica tubes for 350 h at 1070 K, and finally quenched in water. The starting materials were Er 99.82 mass%, Ni 99.99 mass%, and Ge 99.99 mass%.

The ternary phase diagram is characterized by the existence of fourteen ternary compounds and by the formation of substitutional solid solutions originating at  $\text{Er}_2\text{Ni}_{17}$  and  $\text{ErNi}_5$  (10 at.% Ge) as well as  $\text{Er}_5\text{Ge}_3$  (13 at.% Ni). Nonstoichiometry was observed for  $\text{ErNi}_{1-x}\text{Ge}_2$ .

Fig. 105. Er–Ni–Ge, isothermal section at 1070 K.

$\text{ErNi}_5\text{Ge}_3$  (1) was reported to crystallize with the  $\text{YNi}_5\text{Si}_3$  type,  $a=1.903$ ,  $b=0.3847$ ,  $c=0.6783$  by Fedyna et al. (1987). The arc melted alloy, annealed at 1070 K, was investigated by X-ray powder diffraction analysis. The starting materials were Er 99.82 mass%, Ni 99.99 mass%, and Ge 99.99 mass%.

$\text{Er}_3\text{Ni}_{11}\text{Ge}_4$  (2) belongs to the  $\text{Sc}_3\text{Ni}_{11}\text{Si}_4$ -type family of compounds,  $a=0.8273$ ,  $c=0.8680$ , after Fedyna et al. (1987). For the preparation of the alloy, see  $\text{ErNi}_5\text{Ge}_3$ .

Oleksyn and Bodak (1994) used X-ray powder diffraction to investigate the crystal structure of  $\text{ErNi}_3\text{Ge}_2$  (3) which forms a new structure type,  $a=1.79662$ ,  $c=0.379410$ . For alloy synthesis, see Er–Ni–Ge.

The  $\text{ErNi}_2\text{Ge}_2$  (4) compound was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4016$ ,  $c=0.9733$  (Rieger and Parthé 1969b).

$\text{ErNiGe}_3$  (5) with the  $\text{SmNiGe}_3$ -type structure ( $a=0.4013$ ,  $b=0.4031$ ,  $c=2.1396$ , X-ray powder diffraction analysis) was reported by Bodak et al. (1985). For the details of sample preparation and purity of starting materials, see  $\text{SmNiGe}_3$  under Sm–Ni–Ge.

$\text{Er}_2\text{NiGe}_6$  (6) was found to be isostructural with the  $\text{Ce}_2\text{CuGe}_6$ -type structure ( $a=0.39492$ ,  $b=2.1148$ ,  $c=0.39957$ ) by Oleksyn (1990) from X-ray powder diffraction. The sample was prepared by arc melting ingots of the constituting elements and annealing the resulting button at 1070 K for 700 h.

The crystal structure of the  $\text{ErNiGe}_2$  (7) compound was investigated by Oleksyn (1990) from X-ray powder diffraction of arc melted alloys annealed at 1070 K for 350 h. It was found to adopt a  $\text{NdIrGe}_2$ -type structure with lattice parameters  $a=0.4125$ ,  $b=0.8451$ ,  $c=1.5792$ .

Gorelenko et al. (1984) reported the crystal structure of  $\text{ErNiGe}$  (8) ( $\text{TiNiSi}$  type,  $a=0.6818$ ,  $b=0.4188$ ,  $c=0.7239$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

$\text{ErNi}_{0.4}\text{Ge}_{1.6}$  (10) was said to crystallize with the  $\text{AlB}_2$  type structure,  $a=0.40737$ ,  $c=0.39284$  (Oleksyn 1990; X-ray powder diffraction).

Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{ErNi}_{1-x}\text{Ge}_2$  (11) compound by X-ray powder analysis of arc melted alloy annealed at 870 K ( $\text{CeNiSi}_2$  type,  $a=0.3970$ ,  $b=1.5938$ ,  $c=0.3980$ ). Francois et al. (1990) confirmed the structure and reported the composition and lattice parameters  $\text{ErNi}_{0.65}\text{Ge}_2$ ,  $a=0.4068$ ,  $b=1.612$ ,  $c=0.3922$  (X-ray powder diffraction) from a sample obtained by powder metallurgical reaction at 1173 K. Oleksyn (1990) described the limits of the homogeneity field for the compound with the  $\text{CeNiSi}_2$  type structure with the formula  $\text{ErNi}_{0.12-0.36}\text{Ge}_{1.88-1.64}$ ,  $a=0.4078-0.4052$ ,  $b=1.621-1.578$ ,  $c=0.4000-0.3924$ .

$\text{Er}_3\text{Ni}_2\text{Ge}_3$  (12) belongs to the  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  type,  $a=0.41435$ ,  $b=1.0266$ ,  $c=1.3863$  (Oleksyn 1990; X-ray powder diffraction).

Bodak et al. (1982) reported on the crystal structure of the  $\text{Er}_3\text{NiGe}_2$  (13) compound from X-ray powder diffraction ( $\text{La}_3\text{NiGe}_2$  type,  $a=1.1180$ ,  $b=0.4181$ ,  $c=1.1124$ ). The proper amounts of starting components were arc melted and annealed at 870 K.

The crystal structures of two ternary compounds have not been evaluated (Oleksyn 1990):  $\text{Er}_{0.333}\text{Ni}_{0.25}\text{Ge}_{0.417}$  (9),  $\text{Er}_{0.48}\text{Ni}_{0.10}\text{Ge}_{0.42}$  (14).

#### 4.13.6. *Er-Cu-Ge*

No phase diagram is available for the ternary Er-Cu-Ge system, however five ternary compounds were observed and characterized by different groups of authors.

Rieger and Parthé (1969a) investigated the occurrence of the  $AlB_2$ -type structure by means of X-ray powder diffraction of arc melted alloys. The data presented are  $ErCu_{0.67}Ge_{1.33}$  with  $a=0.398$ ,  $c=0.404$ . Iandelli (1993) observed  $ErCuGe$  with the  $CaIn_2$  type ( $a=0.4227$ ,  $c=0.7108$ , X-ray powder analysis). The alloy was prepared from filings or powders of metals (Er 99.7%, Cu and Ge 99.99%), which were mixed and sealed in a tantalum crucible under argon, melted by induction heating, and annealed for 10 days at 1023 K.

$Er_6Cu_8Ge_8$  crystallizes with the  $Gd_6Cu_8Ge_8$ -type structure, lattice parameters  $a=1.3790$ ,  $b=0.6617$ ,  $c=0.4153$  (Rieger 1970).

Konyk et al. (1988) investigated the crystal structure of  $Er_2CuGe_6$  alloy prepared by arc melting under argon and annealing at 870 K in an evacuated quartz tube for 720 h. From X-ray powder analysis the compound was claimed to have the  $Ce_2CuGe_6$ -type structure,  $a=0.3977$ ,  $b=0.4080$ ,  $c=2.0837$ .

Rieger and Parthé (1969b) observed  $ErCu_2Ge_2$  with the  $CeGa_2Al_2$ -type of structure,  $a=0.4003$ ,  $c=1.0317$ .

Francois et al. (1990) observed the  $CeNiSi_2$  type for the  $ErCu_{0.39}Ge_2$  compound and reported the lattice parameters  $a=0.4066$ ,  $b=1.602$ ,  $c=0.3941$  (X-ray powder diffraction) from a sample obtained by a powder metallurgical reaction at 1173 K.

#### 4.13.7. *Er-Nb-Ge*

The phase diagram of the Er-Nb-Ge system has not been yet established. The existence of the compound  $Er_2Nb_3Ge_4$  with the  $Ce_2Sc_3Si_4$ -type structure ( $a=0.6927$ ,  $b=1.3465$ ,  $c=0.7116$ ) was reported by Le Bihan et al. (1996a) from X-ray powder diffraction data of an arc melted alloy. The starting materials were: Er and Nb 99.99 mass%, Ge 99.999 mass%.

#### 4.13.8. *Er-Mo-Ge*

No phase diagram is available for the Er-Mo-Ge system; only one compound was observed and characterized.  $Er_2Mo_3Ge_4$  was reported to crystallize with the  $Ce_2Sc_3Si_4$ -type structure ( $a=0.6863$ ,  $b=1.3070$ ,  $c=0.7028$ ) by Le Bihan et al. (1996b) from X-ray powder diffraction of an arc melted alloy. The starting materials were: Er and Mo 99.99 mass%, Ge 99.999 mass%.

#### 4.13.9. *Er-Ru-Ge*

Early investigations of the  $ErRu_2Ge_2$  compound determined that it had the  $CeGa_2Al_2$ -type structure with  $a=0.4211$ ,  $c=0.9801$  (Francois et al. 1985) from X-ray powder analysis of an alloy obtained by a powder metallurgical reaction at 1273 K. The starting components were Er (3N), Ru (4N), and Ge (4N).

Venturini et al. (1986b) reported the  $\text{Er}_2\text{Ru}_3\text{Ge}_5$  compound to crystallize with the  $\text{U}_2\text{Co}_3\text{Si}_5$ -type structure, lattice parameters  $a=0.9752$ ,  $b=1.240$ ,  $c=0.5696$  (X-ray powder diffraction data). For sample preparation, see  $\text{La}_2\text{Ru}_3\text{Ge}_5$  under La–Ru–Ge.

$\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$  type was announced for the  $\text{Er}_3\text{Ru}_4\text{Ge}_{13}$  compound ( $a=0.8945$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Er (3N), Ru (3N), and Ge (6N).

#### 4.13.10. Er–Rh–Ge

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{Er}_3\text{Rh}_4\text{Ge}_{13}$  compound from a sample prepared by heating a mixture of the starting components (Er 3N, Rh 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to be of the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8904$ .

$\text{Er}_2\text{Rh}_3\text{Ge}_5$  was found to crystallize with  $\text{Lu}_2\text{Co}_3\text{Si}_5$ -type ( $a=0.9933$ ,  $b=1.2025$ ,  $c=0.5808$ ,  $\beta=92.1^\circ$ ; X-ray powder diffraction data) by Venturini et al. (1986b) from an alloy which was synthesized by a powder metallurgical reaction at 1173 K. The purity of the starting materials was greater than 99.9 mass%.

$\text{Er}_4\text{Rh}_7\text{Ge}_6$  was reported to adopt  $\text{U}_4\text{Re}_7\text{Si}_6$ -type structure ( $a=0.8296$ ; Francois et al. 1985) from a sample which was obtained by heating a mixture of powders of the starting materials (Er 3N, Rh 4N, Ge 4N) in an evacuated quartz tube at 1273 K.

Gladyshevsky et al. (1991a) reported on the crystal structure of the  $\text{Er}_3\text{Rh}_2\text{Ge}_2$  compound ( $\text{La}_3\text{Ni}_2\text{Ge}_2$  type,  $a=0.55207$ ,  $b=0.7683$ ,  $c=1.3138$ ; X-ray powder diffraction data). For the details of sample preparation, see  $\text{La}_3\text{Rh}_2\text{Ge}_2$  under La–Rh–Ge.

Verniere et al. (1995) established that the compound  $\text{Er}_4\text{Rh}_{13}\text{Ge}_9$  is of the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$  type. No lattice parameters were given. For sample preparation, see  $\text{La}_4\text{Ir}_{13}\text{Ge}_9$  under La–Ir–Ge.

$\text{Er}_2\text{Rh}_3\text{Ge}$  crystallizes with the  $\text{Y}_2\text{Rh}_3\text{Ge}$ -type of structure, lattice parameters  $a=0.5523$ ,  $c=1.1762$  (Cenzual et al. 1987). The sample was obtained by arc melting under argon and annealing at 1273 K for 7 days.

Méot-Meyer et al. (1985b) reported the existence of the  $\text{Er}_5\text{Rh}_4\text{Ge}_{10}$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure, but no lattice parameters were given.

Francois et al. (1985) determined the  $\text{CeGa}_2\text{Al}_2$  type for the  $\text{ErRh}_2\text{Ge}_2$  compound,  $a=0.4094$ ,  $c=1.0170$ .

Hovestreydt et al. (1982) reported the crystal structure of the  $\text{ErRhGe}$  compound ( $\text{TiNiSi}$  type,  $a=0.6827$ ,  $b=0.4257$ ,  $c=0.7507$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. The starting components were Er (3N), Rh (4N), and Ge (5N).

#### 4.13.11. Er–Pd–Ge

No systematic study of the Er–Pd–Ge system has been performed; the existence of three ternary compounds has been observed by different groups of authors.

Sologub et al. (1995a) reported an X-ray powder analysis of the  $\text{Er}_2\text{PdGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.40574$ ,  $b=0.40051$ ,  $c=2.1402$ . For the experimental procedure, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge. The starting materials used were obtained from Johnson & Matthey, UK (99.9%).

The crystal structure of the compound  $\text{ErPd}_2\text{Ge}$  was found to be of the  $\text{YPd}_2\text{Si}$  type ( $a=0.7296$ ,  $b=0.7038$ ,  $c=0.5551$ ; X-ray powder diffraction) by Jorda et al. (1983). For the experimental procedure, see  $\text{LaPd}_2\text{Ge}$  under La–Pd–Ge. The starting materials were Pd 99.99 mass%, Ge specre quality, and Er 99.9 mass%.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound  $\text{ErPdGe}$  adopts the  $\text{KHg}_2$ -type structure,  $a=0.4348$ ,  $b=0.6900$ ,  $c=0.7536$ . For sample preparation, see  $\text{LaPdGe}$  under La–Pd–Ge. The starting materials were Er (3N), Pd (4N), and Ge (5N).

#### 4.13.12. *Er–Ag–Ge*

No ternary phase diagram has been established for the Er–Ag–Ge system, however one ternary compound has been characterized. Gibson et al. (1996) reported an X-ray single-crystal investigation of the  $\text{ErAgGe}$  compound. It was found to adopt the  $\text{ZrNiAl}$  type,  $a=0.70649$ ,  $c=0.41665$ . The single crystal was isolated from an arc melted sample annealed at 970 K for ten days.

#### 4.13.13. *Er–Os–Ge*

No phase diagram exists for the ternary Er–Os–Ge system; four ternary compounds have been observed and studied. The  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type was announced for the  $\text{Er}_3\text{Os}_4\text{Ge}_{13}$  compound ( $a=0.8973$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Er (3N), Os (3N), and Ge (6N).

Méot-Meyer et al. (1985b) observed the existence of the  $\text{Er}_5\text{Os}_4\text{Ge}_{10}$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure from X-ray powder diffraction of a sample obtained by heating in an evacuated tube at 1073 K. However, no lattice parameters were reported.

$\text{Er}_4\text{Os}_7\text{Ge}_6$  was reported to adopt the  $\text{U}_4\text{Re}_7\text{Si}_6$ -type structure ( $a=0.8314$ ; Francois et al. 1985) from a sample obtained by heating a mixture of powders of the starting materials (Er 3N, Os 4N, Ge 4N) in an evacuated quartz tube at 1273 K.

$\text{ErOsGe}_2$  belongs to the  $\text{TiMnSi}_2$ -type,  $a=0.957$ ,  $b=1.055$ ,  $c=0.829$  (Venturini et al. 1985b; X-ray powder diffraction). The alloy was synthesized by a powder metallurgical reaction and annealed at 1073 K.

#### 4.13.14. *Er–Ir–Ge*

No ternary phase diagram has been established for the Er–Ir–Ge system, however six ternary compounds have been characterized.

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{Er}_3\text{Ir}_4\text{Ge}_{13}$  compound from a sample which was prepared by heating a mixture of the starting

components (Er 3N, Ir 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to be of the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8923$ .

Verniere et al. (1995) reported the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type structure for the  $\text{Er}_4\text{Ir}_{13}\text{Ge}_9$  compound. No lattice parameters were given. For the experimental procedure, see  $\text{La}_4\text{Ir}_{13}\text{Ge}_9$  under La–Ir–Ge.

Hovestreydt et al. (1982) reported the crystal structure of the ErIrGe compound (TiNiSi type,  $a=0.6766$ ,  $b=0.4238$ ,  $c=0.7593$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. The starting components were Er (3N), Ir (4N), and Ge (5N).

Francois et al. (1987) reported the crystal structure of  $\text{ErIrGe}_2$  (NdIrGe<sub>2</sub> type,  $a=0.4227$ ,  $b=1.594$ ,  $c=0.8783$ ). The sample was prepared by heating a mixture of powders of the starting components (Er 3N, Ir 3N, Ge 3N) in an evacuated silica tube at 1173 K.

Méot-Meyer et al. (1985b) observed the existence of the  $\text{Er}_5\text{Ir}_4\text{Ge}_{10}$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$  type from a sample obtained by heating in an evacuated tube at 1073 K. However, no lattice parameters were given.

$\text{Er}_4\text{Ir}_7\text{Ge}_6$  was reported to adopt  $\text{U}_4\text{Re}_7\text{Si}_6$ -type structure ( $a=0.8295$ ; Francois et al. 1985) from a sample which was obtained by heating a mixture of powders of the starting materials (Er 3N, Ir 4N, Ge 4N) in an evacuated quartz tube at 1273 K.

#### 4.13.15. Er–Pt–Ge

No phase diagram has been established for the Er–Pt–Ge system. Two ternary compounds were observed by different authors.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound ErPtGe adopts the TiNiSi-type structure,  $a=0.6917$ ,  $b=0.4319$ ,  $c=0.7527$ . For sample preparation, see LaPdGe under La–Pd–Ge.

Sologub et al. (1995a) reported an X-ray powder analysis of the  $\text{Er}_2\text{PtGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.40315$ ,  $b=0.39977$ ,  $c=2.1573$ . For sample preparation, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge.

#### 4.13.16. Er–Au–Ge

Information on interaction of erbium with gold and germanium is due to Rossi et al. (1992). The phase diagram of the Er–Au–Ge system is not available. A ternary compound of erbium with gold and germanium of the stoichiometric 1:1:1 ratio has been identified and studied by means of X-ray and metallographic analyses by Rossi et al. (1992). ErAuGe was found to adopt the LiGaGe type with lattice parameters  $a=0.4397$ ,  $c=0.7203$ . For the experimental procedure, see GdAuGe under Gd–Au–Ge.

### 4.14. Tm–d element–Ge systems

#### 4.14.1. Tm–Mn–Ge

No systematic study has been performed for the Tm–Mn–Ge system; however, the formation of two ternary compounds has been reported so far.

$\text{TmMn}_6\text{Ge}_6$  was found to crystallize in the  $\text{HfFe}_6\text{Ge}_6$ -type structure by Venturini et al. (1992),  $a=0.5219$ ,  $c=0.8139$  (X-ray powder diffraction data). The alloy was synthesized by a powder metallurgical reaction in an evacuated silica tube at 1073 K for 14 days.

$\text{TmMn}_{0.25}\text{Ge}_2$  compound was found to adopt the  $\text{CeNiSi}_2$ -type structure with lattice parameters  $a=0.4073$ ,  $b=1.557$ ,  $c=0.3966$  by Francois et al. (1990) (X-ray powder diffraction data). For sample preparation, see  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$  under Gd-Fe-Ge.

#### 4.14.2. Tm-Fe-Ge

The phase diagram of the Tm-Fe-Ge system was investigated by Fedyna (1988) by means of metallographic and X-ray phase analyses (fig. 106). Alloys for investigation were prepared by arc melting followed by annealing at 870 K for 500 hours. The purity of the starting components was greater than 99.9 mass%. Ten ternary compounds were observed.

$\text{TmFe}_6\text{Ge}_6$  (1) was reported to be isotypic with the crystal structure of  $\text{YCo}_6\text{Ge}_6$ , lattice parameters  $a=0.5143$ ,  $c=0.4098$  (Mruz et al. 1984). The sample was prepared by arc melting the proper amounts of the starting components followed by annealing at 870 K for two weeks. At variance with these data,  $\text{TmFe}_6\text{Ge}_6$  was found to crystallize with the  $\text{HoFe}_6\text{Sn}_6$ -type structure,  $a=0.8095$ ,  $b=2.653$ ,  $c=0.5107$ , by Venturini et al. (1992) from X-ray powder diffraction data. The alloy was obtained by powder metallurgical reaction in an evacuated silica tube at 1173 K for two weeks. These results suggest that  $\text{TmFe}_6\text{Ge}_6$  may be polymorphic.

$\text{TmFe}_4\text{Ge}_2$  (2) was found to crystallize in the  $\text{ZrFe}_4\text{Si}_2$ -type structure,  $a=0.72228$ ,  $c=0.37456$ , by Fedyna (1988) in the course of a phase diagram investigation employing X-ray powder diffraction.

According to X-ray powder diffraction data,  $\text{TmFe}_2\text{Ge}_2$  (4) is isostructural with

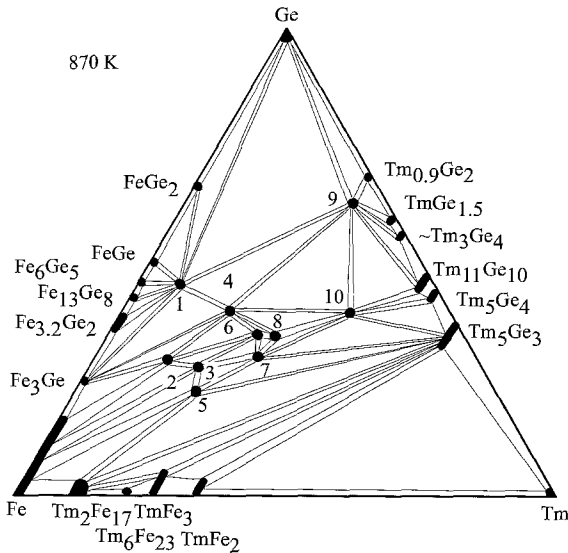

Fig. 106. Tm-Fe-Ge, isothermal section at 870 K.

$\text{CeGa}_2\text{Al}_2$ , lattice parameters  $a=0.39301$ ,  $c=1.04184$  (Fedyna 1988; X-ray powder diffraction).

Fedyna (1988) investigated the crystal structure of  $\text{Tm}_9\text{Fe}_{10}\text{Ge}_{10}$  (8) by a single-crystal method. It was found to crystallize with a new structure type,  $a=0.5386$ ,  $b=1.3306$ ,  $c=1.3913$ . The single crystal was isolated from an alloy which was arc melted and annealed at 870 K.

Pecharsky et al. (1989) reported  $\text{TmFe}_{1-x}\text{Ge}_2$  (9) to crystallize with the  $\text{CeNiSi}_2$ -type structure ( $a=0.4061\text{--}0.4066$ ,  $b=1.5532\text{--}1.5610$ ,  $c=0.3959\text{--}0.3961$ ; X-ray powder analysis). The alloy was arc melted and annealed at 870 K. The purity of the starting materials was greater than 99.9 mass%. Francois et al. (1990) confirmed the occurrence of the  $\text{CeNiSi}_2$  type for thulium–iron–germanium combinations from alloys annealed at 1173 K ( $\text{TmFe}_{0.35}\text{Ge}_2$ ;  $a=0.4082$ ,  $b=1.558$ ,  $c=0.3973$ ).

Fedyna (1988) investigated the crystal structure of the  $\text{Tm}_{117}\text{Fe}_{52}\text{Ge}_{112}$  (10) compound by X-ray powder diffraction ( $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$  structure type,  $a=2.7964$ ). The alloy was synthesized by arc melting and annealing a melted button at 870 K for 350 h. The starting materials were Tm 99.83 mass%, Fe 99.9 mass%, and Ge 99.99 mass%.

Four more ternary compounds with unknown structure were observed by Fedyna (1988) at 870 K:  $\sim\text{Tm}_{0.20}\text{Fe}_{0.53}\text{Ge}_{0.27}$  (3),  $\sim\text{Tm}_{0.225}\text{Fe}_{0.55}\text{Ge}_{0.225}$  (5),  $\sim\text{Tm}_{0.275}\text{Fe}_{0.375}\text{Ge}_{0.35}$  (6) and  $\sim\text{Tm}_{0.30}\text{Fe}_{0.40}\text{Ge}_{0.30}$  (7).

#### 4.14.3. *Tm–Co–Ge*

Isothermal sections of the Tm–Co–Ge system at 870 K (33–100 at.% Tm) and at 1070 K (0–33 at.% Tm) were derived by Fedyna (1988) (fig. 107) employing X-ray phase and

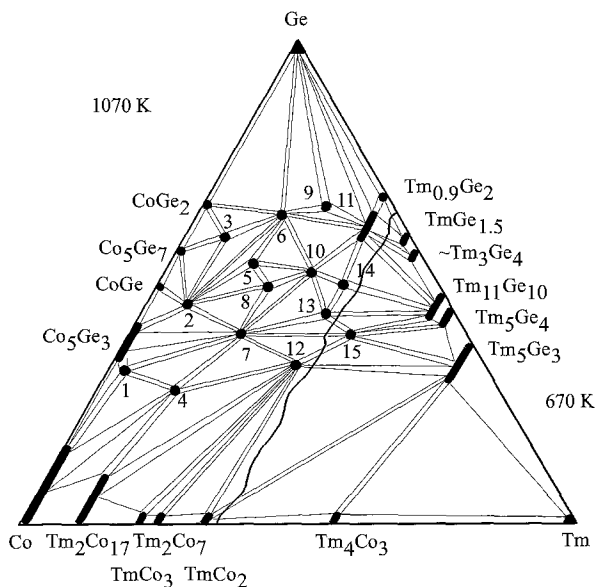

Fig. 107. Tm–Co–Ge, isothermal sections at 1070 K (0–33 at.% Tm) and at 670 K (33–100 at.% Tm).

microstructural analyses of 145 alloys prepared by arc melting the proper amounts of the constituent elements of high purity. The melted buttons were then annealed in evacuated silica tubes for 500 hours. Fifteen ternary compounds were found to exist.

The crystal structure of the  $\text{TmCo}_6\text{Ge}_6$  (2) compound was reported by Buchholz and Schuster (1981) ( $\text{YCo}_6\text{Ge}_6$  structure type,  $a=0.5098$ ,  $c=0.3912$ ). The sample was melted under argon in a corundum crucible at 1073–1273 K.

$\text{TmCo}_4\text{Ge}_2$  (4) was found to form the  $\text{ZrFe}_4\text{Si}_2$ -type structure,  $a=0.72285$ ,  $c=0.37456$ , by Fedyna (1988) employing X-ray powder diffraction.

Méot-Meyer et al. (1985a) reported the crystal structure of  $\text{TmCo}_x\text{Ge}_2$  (11),  $x=0.42$  ( $\text{CeNiSi}_2$  type,  $a=0.4070$ ,  $b=1.578$ ,  $c=0.3988$ ). The sample was prepared by a powder metallurgical reaction and annealed in an evacuated silica tube at 1173 K. Pecharsky et al. (1989) confirmed the formation and crystal structure of the  $\text{TmCo}_x\text{Ge}_2$  compound from arc melted alloys annealed at 870 K ( $a=0.4062$ – $0.4079$ ,  $b=1.5613$ – $1.5760$ ,  $c=0.3965$ – $0.3977$ ; X-ray powder analysis).

The crystal structure of  $\text{Tm}_3\text{Co}_4\text{Ge}_{13}$  (6) ( $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8715$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample which was prepared by heating a compacted mixture of the starting materials (Tm in pieces, 99.9 mass%; Co and Ge in powder, 99.99 mass%) in an evacuated quartz tube at 1073 K. Bodak et al. (1987) reported the  $\text{Y}_3\text{Co}_4\text{Ge}_{13}$ -type structure for the  $\text{Tm}_3\text{Co}_4\text{Ge}_{13}$  compound ( $a=0.87156$ ; X-ray powder data) from an arc melted alloy annealed at 870 K.

$\text{TmCo}_2\text{Ge}_2$  (7) was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4259$ ,  $c=1.1060$  (Fedyna 1988; X-ray powder diffraction).

$\text{Tm}_2\text{CoGe}_6$  is isotypic with  $\text{Ce}_2\text{CuGe}_6$  (9),  $a=0.3909$ ,  $b=0.3951$ ,  $c=2.1252$  (Oleksyn et al. 1991; X-ray powder diffraction data). The sample was melted in an arc furnace and annealed at 1070 K in an evacuated quartz capsule for 400 h. The purity of the starting materials was greater than 99.9 mass%.

$\text{Tm}_5\text{Co}_4\text{Ge}_{10}$  (10) has the  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure,  $a=1.2622$ ,  $c=0.4139$ , after Venturini et al. (1984).

Gorelenko et al. (1984) reported the crystal structure of  $\text{TmCoGe}$  (12) ( $\text{TiNiSi}$  type,  $a=0.6775$ ,  $b=0.4168$ ,  $c=0.7224$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

$\text{Tm}_3\text{Co}_2\text{Ge}_4$  (13) crystallizes with the  $\text{Tb}_3\text{Co}_2\text{Ge}_4$ -type structure,  $a=1.0410$ ,  $b=0.7904$ ,  $c=0.4143$ ,  $\gamma=107.04^\circ$  (X-ray powder diffraction data; Mruz et al. (1989). The sample was prepared by arc melting and annealing at 873 K for 240 h.

Bodak et al. (1986) reported an X-ray powder investigation of the compound  $\text{Tm}_2\text{CoGe}_2$  (15):  $\text{Sc}_2\text{CoSi}_2$ -type structure,  $a=1.0326$ ,  $b=1.0125$ ,  $c=0.4119$ ,  $\gamma=117.00^\circ$ .

In the course of phase diagram studies, Fedyna (1988) observed five more ternary compounds with unknown structures:  $\sim\text{Tm}_{0.03}\text{Co}_{0.65}\text{Ge}_{0.32}$  (1),  $\sim\text{Tm}_{0.07}\text{Co}_{0.33}\text{Ge}_{0.60}$  (3),  $\sim\text{Tm}_{0.15}\text{Co}_{0.30}\text{Ge}_{0.55}$  (5),  $\sim\text{Tm}_{0.20}\text{Co}_{0.30}\text{Ge}_{0.50}$  (8) and  $\sim\text{Tm}_{0.33}\text{Co}_{0.17}\text{Ge}_{0.50}$  (14).

#### 4.14.4. *Tm–Ni–Ge*

Figure 108 represents the isothermal sections of the Tm–Ni–Ge system at 870 K (0–50 at.% Tm) and at 670 K (50–100 at.% Tm), studied by Fedyna (1988). The isothermal

Fig. 108. Tm-Ni-Ge, isothermal sections at 870 K (0–50 at.% Tm) and at 670 K (50–100 at.% Tm).

sections were constructed by means of X-ray powder and metallographic analyses of 200 alloys which were arc melted, subsequently annealed in evacuated silica tubes for 900 h, and finally quenched in water. The starting materials were Tm 99.82 mass%, Ni 99.98 mass% and Ge 99.99 mass%.

The ternary phase diagram is characterized by the existence of twelve ternary compounds and by the formation of substitutional solid solutions based at  $\text{Tm}_2\text{Ni}_{17}$  (10 at.% Ge) and  $\text{TmNi}_5$  (15 at.% Ge). The binary compounds  $\text{Tm}_5\text{Ge}_3$  and  $\text{Tm}_{11}\text{Ge}_{10}$  dissolve 13 and 8 at.% Ni, respectively.

$\text{TmNi}_5\text{Ge}_3$  (1) was reported to crystallize with the  $\text{YNi}_5\text{Si}_3$  type,  $a = 1.90183$ ,  $b = 0.38398$ ,  $c = 0.67867$ , by Fedyna (1988). The arc melted alloy, annealed at 870 K, was investigated by X-ray powder diffraction analysis. The starting materials were Tm 99.82 mass%, Ni 99.99 mass%, and Ge 99.99 mass%.

$\text{Tm}_3\text{Ni}_{11}\text{Ge}_4$  (2) belongs to the  $\text{Sc}_3\text{Ni}_{11}\text{Si}_4$ -type structure group of compounds,  $a = 0.8279$ ,  $c = 0.8690$ , after Fedyna et al. (1987). The alloy was prepared in the same manner as  $\text{TmNi}_5\text{Ge}_3$ .

The  $\text{TmNi}_{2-1.56}\text{Ge}_{2-2.20}$  (4) compound was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a = 0.4003-0.3985$ ,  $c = 0.9724-0.9596$  (Fedyna 1988).

$\text{TmNiGe}_3$  (5) with the  $\text{ScNiSi}_3$ -type structure ( $a = 2.1372$ ,  $b = 0.4019$ ,  $c = 0.4003$ , X-ray powder diffraction analysis) was reported by Bodak et al. (1985). For the details of sample preparation and the purity of the starting materials, see  $\text{TmNi}_5\text{Ge}_3$ .

$\text{Tm}_2\text{NiGe}_6$  (6) has been found by Oleksyn (1990) from X-ray powder diffraction to be isostructural with  $\text{Ce}_2\text{CuGe}_6$ -type structure ( $a = 0.3931$ ,  $b = 2.1031$ ,  $c = 0.3979$ ). The

sample was prepared by arc melting ingots of the constituting elements and annealing at 1070 K for 700 h. For the purity of starting materials, see  $\text{TmNi}_5\text{Ge}_3$ .

Oleksyn (1990) reported the crystal structure of the  $\text{TmNiGe}_2$  (7) compound,  $\text{NdIrGe}_2$  type,  $a=0.4095$ ,  $b=0.8405$ ,  $c=1.5779$ , from X-ray powder diffraction analysis. For the experimental procedure, see  $\text{Tm}_2\text{NiGe}_6$ .

Gorelenko et al. (1984) investigated the crystal structure of  $\text{TmNiGe}$  (9) ( $\text{TiNiSi}$  type,  $a=0.6790$ ,  $b=0.4183$ ,  $c=0.7235$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours. According to DTA, this phase exhibits polymorphism at 1630 K (Koterlyn et al. 1994).

$\text{Tm}(\text{Ni}_{0.23-0.165}\text{Ge}_{0.60-0.665})_{2-x}$  (11),  $x=0.34$ , was said to form an  $\text{AlB}_2$  type,  $a=0.40795-0.40706$ ,  $c=0.39238-0.40084$  (Fedyna 1988; X-ray powder diffraction).

Four more ternary compounds with unknown structures were observed by Fedyna (1988) in the  $\text{Tm-Ni-Ge}$  system:  $\sim\text{Tm}_{0.17}\text{Ni}_{0.53}\text{Ge}_{0.30}$  (3),  $\sim\text{Tm}_{0.27}\text{Ni}_{0.28}\text{Ge}_{0.45}$  (8),  $\sim\text{Tm}_{0.33}\text{Ni}_{0.27}\text{Ge}_{0.40}$  (10) and  $\sim\text{Tm}_{0.50}\text{Ni}_{0.32}\text{Ge}_{0.18}$  (12).

Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{TmNi}_{1-x}\text{Ge}_2$  compound by X-ray powder analysis of arc melted alloy annealed at 870 K ( $\text{CeNiSi}_2$  type,  $a=0.4015-0.4071$ ,  $b=1.5728-1.6023$ ,  $c=0.3881-0.3979$ ). For sample preparation, see  $\text{TmNi}_5\text{Ge}_3$ . Francois et al. (1990) confirmed the structure and reported the composition and lattice parameters  $\text{TmNi}_{0.42}\text{Ge}_2$ ,  $a=0.4070$ ,  $b=1.578$ ,  $c=0.3988$  (X-ray powder diffraction) from a sample obtained by powder metallurgical reaction at 1173 K.

#### 4.14.5. *Tm-Cu-Ge*

No isothermal section is available for the ternary  $\text{Tm-Cu-Ge}$  system; however five ternary compounds were observed and characterized by different groups of authors.

Rieger and Parthé (1969a) investigated the occurrence of the  $\text{AlB}_2$ -type structure by means of X-ray powder diffraction of arc melted alloys. The data presented were  $\text{TmCu}_{1-0.67}\text{Ge}_{1-1.33}$  with  $a=0.4220-0.397$ ,  $c=0.3545-0.397$ . At variance with the data of Rieger and Parthé (1969a), Iandelli (1993) observed  $\text{TmCuGe}$  with the  $\text{CaIn}_2$ -type ( $a=0.4225$ ,  $c=0.7045$ , X-ray powder analysis). The alloy was prepared from turnings or powders of metals (thulium 99.7 mass%, copper and germanium 99.99 mass%), which were mixed and sealed in a tantalum crucible under argon, melted by induction heating, and annealed for 10 days at 1023 K.

$\text{Tm}_6\text{Cu}_8\text{Ge}_8$  crystallizes with the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$ -type structure, lattice parameters  $a=1.374$ ,  $b=0.660$ ,  $c=0.413$  (Hanel and Nowotny 1970).

Konyk et al. (1988) investigated the crystal structure of  $\text{Tm}_2\text{CuGe}_6$  which had been prepared by arc melting the starting components under argon and annealing at 870 K in an evacuated quartz tube for 720 h. From X-ray powder analysis the  $\text{Ce}_2\text{CuGe}_6$ -type structure was claimed for this compound,  $a=0.4065$ ,  $b=0.3963$ ,  $c=2.0767$ .

Rieger and Parthé (1969b) prepared  $\text{TmCu}_2\text{Ge}_2$  with the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.3994$ ,  $c=1.0307$ .

Francois et al. (1990) observed the  $\text{CeNiSi}_2$ -type structure for the  $\text{TmCu}_{0.20}\text{Ge}_2$  compound and reported the lattice parameters  $a=0.4055$ ,  $b=1.585$ ,  $c=0.3931$  (X-ray

powder diffraction) from a sample obtained by a powder metallurgical reaction at 1173 K.

#### 4.14.6. *Tm-Nb-Ge*

The phase diagram of the Tm-Nb-Ge system has not been established. The existence of the compound  $\text{Tm}_2\text{Nb}_3\text{Ge}_4$  with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$  type ( $a=0.6917$ ,  $b=1.3416$ ,  $c=0.7092$ ) was reported by Le Bihan et al. (1996a) from X-ray powder diffraction data of arc melted alloy. Starting materials were: Tm and Nb 99.99 mass%, Ge 99.999 mass%.

#### 4.14.7. *Tm-Mo-Ge*

No phase diagram is available for the Tm-Mo-Ge system, and only one compound was observed and investigated.  $\text{Tm}_2\text{Mo}_3\text{Ge}_4$  was reported to crystallize with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$ -type structure ( $a=0.6840$ ,  $b=1.3041$ ,  $c=0.7009$ ) by Le Bihan et al. (1996b) from X-ray powder diffraction of an arc melted alloy. The starting materials were: Tm and Mo 99.99 mass%, Ge 99.999 mass%.

#### 4.14.8. *Tm-Ru-Ge*

X-ray powder analysis of an alloy with the  $\text{TmRu}_2\text{Ge}_2$  composition showed that it had the  $\text{CeGa}_2\text{Al}_2$ -type structure with  $a=0.4202$ ,  $c=0.9797$  (Francois et al. 1985). The sample was obtained by a powder metallurgical reaction at 1273 K. The starting components were Tm (3N), Ru (4N), and Ge (4N).

Venturini et al. (1986b) reported on  $\text{Tm}_2\text{Ru}_3\text{Ge}_5$  crystallizing with the  $\text{U}_2\text{Co}_3\text{Si}_5$  type. Lattice parameters were reported as  $a=0.9725$ ,  $b=1.239$ ,  $c=0.5676$  (X-ray powder diffraction data). For sample preparation, see  $\text{La}_2\text{Ru}_3\text{Ge}_5$  under La-Ru-Ge.

$\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type was reported for the  $\text{Tm}_3\text{Ru}_4\text{Ge}_{13}$  compound ( $a=0.8925$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Tm (3N), Ru (3N), and Ge (6N).

#### 4.14.9. *Tm-Rh-Ge*

Venturini et al. (1985b) reported an X-ray powder diffraction study of the crystal structure of  $\text{Tm}_3\text{Rh}_4\text{Ge}_{13}$  from an alloy which was prepared by heating a mixture of the starting components (Tm 3N, Rh 4N, Ge 4N) in an evacuated quartz tube at 1073 K. It was found to adopt the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$ -type structure,  $a=0.8899$ .

Francois et al. (1985) determined the  $\text{CeGa}_2\text{Al}_2$  type for the  $\text{TmRh}_2\text{Ge}_2$  compound,  $a=0.4062$ ,  $c=1.0129$ .

$\text{Tm}_2\text{Rh}_3\text{Ge}_5$  was found to crystallize with  $\text{Lu}_2\text{Co}_3\text{Si}_5$ -type structure ( $a=0.9903$ ,  $b=1.2009$ ,  $c=0.5781$ ,  $\beta=92.4^\circ$ ; X-ray powder diffraction data) by Venturini et al. (1986b) from a sample prepared by a powder metallurgical reaction at 1173 K. The purity of the starting materials was greater than 99.9 mass%.

Gladyshevsky et al. (1991a) reported on the crystal structure of the  $\text{Tm}_3\text{Rh}_2\text{Ge}_2$  compound ( $\text{La}_3\text{Ni}_2\text{Ge}_2$  type,  $a=0.550897$ ,  $b=0.7654$ ,  $c=1.3097$ ; X-ray powder diffraction data). For the details of sample preparation, see  $\text{La}_3\text{Rh}_2\text{Ge}_2$  under La–Rh–Ge.

Verniere et al. (1995) observed that the compound  $\text{Tm}_4\text{Rh}_{13}\text{Ge}_9$  belonged to the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type structure. No lattice parameters were reported. For sample preparation, see  $\text{La}_4\text{Ir}_{13}\text{Ge}_9$  under La–Ir–Ge.

Venturini et al. (1984) established the existence of the  $\text{Tm}_5\text{Rh}_4\text{Ge}_{10}$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure,  $a=1.2868$ ,  $c=0.4230$ , from X-ray powder analysis of a sample obtained by heating a mixture of powders in an evacuated tube at 1073 K.

$\text{Tm}_4\text{Rh}_7\text{Ge}_6$  belongs to the  $\text{U}_4\text{Re}_7\text{Si}_6$ -type structure group,  $a=0.8276$  (Francois et al. 1985; X-ray powder diffraction). The alloy was synthesized by heating a mixture of powders of the constituent elements in an evacuated quartz tube at 1273 K. The starting components were Tm (3N), Rh (4N), and Ge (4N).

#### 4.14.10. *Tm–Pd–Ge*

No systematic study of the Tm–Pd–Ge system has been performed, but the existence of three ternary compounds has been observed by different groups of authors.

Sologub et al. (1995a) reported an X-ray powder analysis of the  $\text{Tm}_2\text{PdGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.4047$ ,  $b=0.3995$ ,  $c=2.1346$ . For the experimental procedure, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge. The purity of the starting materials used was 99.9 mass%.

The crystal structure of the compound  $\text{TmPd}_2\text{Ge}$  was found to be of the  $\text{YPd}_2\text{Si}$  type ( $a=0.7254$ ,  $b=0.7045$ ,  $c=0.5523$ ; X-ray powder diffraction) by Jorda et al. (1983). For the experimental procedure, see  $\text{LaPd}_2\text{Ge}$  under La–Pd–Ge. The starting materials were Pd 99.99 mass%, Ge specpure quality, and Tm 99.9 mass%.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound  $\text{TmPdGe}$  adopts the  $\text{KHg}_2$ -type structure,  $a=0.4337$ ,  $b=0.6855$ ,  $c=0.7524$ . For sample preparation, see  $\text{LaPdGe}$  under La–Pd–Ge. The starting metals were Tm (3N), Pd (4N), and Ge (5N).

#### 4.14.11. *Tm–Ag–Ge*

No ternary phase diagram has been established for the Tm–Ag–Ge system, however one ternary compound has been characterized. Gibson et al. (1996) reported an X-ray powder investigation of the  $\text{TmAgGe}$  compound. It was found to adopt the  $\text{ZrNiAl}$ -type structure,  $a=0.70415$ ,  $c=0.41570$ . The sample was arc melted and annealed at 970 K for ten days.

#### 4.14.12. *Tm–Os–Ge*

No phase diagram is available for the ternary Tm–Os–Ge system; four ternary compounds have been observed.  $\text{Tm}_4\text{Os}_7\text{Ge}_6$  belongs to the  $\text{U}_4\text{Re}_7\text{Si}_6$ -type structure group of compounds,  $a=0.8297$  (Francois et al. 1985; X-ray powder diffraction). The alloy was synthesized by heating a mixture of powders of the constituent elements in an evacuated quartz tube at 1273 K. The starting components were Tm (3N), Os (4N), and Ge (4N).

The  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type structure was reported for the  $\text{Tm}_3\text{Os}_4\text{Ge}_{13}$  compound ( $a=0.8955$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Tm (3N), Os (3N), and Ge (6N).

Venturini et al. (1984) observed the existence of the  $\text{Tm}_5\text{Os}_4\text{Ge}_{10}$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure,  $a=1.2929$ ,  $c=0.4253$ , from a sample obtained by heating a compacted mixture of powders of the starting metals in an evacuated tube at 1073 K.

$\text{TmOsGe}_2$  is isostructural with  $\text{TiMnSi}_2$ ,  $a=0.953$ ,  $b=1.052$ ,  $c=0.827$  (Venturini et al. 1985b; X-ray powder diffraction). The alloy was obtained by a powder metallurgical reaction and annealed at 1073 K.

#### 4.14.13. *Tm-Ir-Ge*

No ternary phase diagram has been established for the Tm-Ir-Ge system, however five ternary compounds have been characterized.

Méot-Meyer et al. (1985b) observed the existence of the  $\text{Tm}_5\text{Ir}_4\text{Ge}_{10}$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure from samples obtained by heating compacted mixtures of the proper amounts of the starting metals in evacuated tubes at 1073 K.

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{Tm}_3\text{Ir}_4\text{Ge}_{13}$  compound from a sample which was prepared in the same way as  $\text{Tm}_5\text{Ir}_4\text{Ge}_{10}$ . The starting components were Tm (3N), Ir (4N), and Ge (4N). The crystal structure was found to be of the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8912$ .

Hovestreydt et al. (1982) reported the crystal structure of the  $\text{TmIrGe}$  compound (TiNiSi type,  $a=0.6736$ ,  $b=0.4227$ ,  $c=0.7591$ ; X-ray powder data) from an arc melted sample annealed at 1270 K for 1–2 weeks. The starting components were Tm (3N), Ir (4N), and Ge (5N).

Verniere et al. (1995) suggested the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$ -type structure for the  $\text{Tm}_4\text{Ir}_{13}\text{Ge}_9$  compound. No lattice parameters were given. For the experimental procedure, see  $\text{La}_4\text{Ir}_{13}\text{Ge}_9$  under La-Ir-Ge.

$\text{Tm}_4\text{Ir}_7\text{Ge}_6$  was reported to adopt the  $\text{U}_4\text{Re}_7\text{Si}_6$ -type structure ( $a=0.8273$ ; Francois et al. 1985) from a sample which was obtained by heating a mixture of powders of the starting materials (Tm 3N, Ir 3N, Ge 4N) in an evacuated quartz tube at 1273 K.

#### 4.14.14. *Tm-Pt-Ge*

No phase diagram has been established for the Tm-Pt-Ge system. Three ternary compounds were observed by different scientific groups.

According to an X-ray powder diffraction analysis reported by Hovestreydt et al. (1982), the compound  $\text{TmPtGe}$  adopts the TiNiSi-type structure,  $a=0.6880$ ,  $b=0.4306$ ,  $c=0.7517$ . For sample preparation, see  $\text{LaPdGe}$  under La-Pd-Ge.

Sologub et al. (1995a) reported an X-ray powder analysis of the  $\text{Tm}_2\text{PtGe}_6$  compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.4048$ ,  $b=0.3993$ ,  $c=2.1539$ . For sample preparation, see  $\text{La}_2\text{PdGe}_6$  under La-Pd-Ge.

Francois et al. (1987) observed the existence of  $\text{TmPtGe}_2$  with the  $\text{NdIrGe}_2$ -type structure. The lattice parameters were measured as  $a = 0.4263$ ,  $b = 1.620$ ,  $c = 0.8657$ . The sample was prepared by heating a mixture of powders of the starting components (Tm 3N, Pt 3N, Ge 3N) in an evacuated silica tube at 1173 K.

#### 4.14.15. *Tm–Au–Ge*

The only information on the interaction of components in the ternary Tm–Au–Ge system is due to Pöttgen et al. (1996a) who observed and characterized the  $\text{TmAuGe}$  compound. The LiGaGe-type structure was claimed with lattice parameters  $a = 0.43907$ ,  $c = 0.71659$  (X-ray single-crystal data). The sample was obtained by melting a mixture of the metals in an arc furnace and annealing at 1070 K for one week.

#### 4.15. *Yb–d element–Ge systems*

##### 4.15.1. *Yb–Mn–Ge*

The isothermal section for the Yb–Mn–Ge system at 670 K was established by Dzianii (1995) who employed X-ray powder analysis of 84 samples obtained by arc melting the proper amounts of starting components and annealing at 670 K for twenty days. The phase-field relations are characterized by the existence of three ternary compounds (fig. 109). The solubility of a third component in the binary compounds was found to be negligible.

$\text{YbMn}_6\text{Ge}_6$  (1) was found to crystallize with the  $\text{HfFe}_6\text{Ge}_6$ -type structure by Venturini et al. (1992),  $a = 0.5212$ ,  $c = 0.8132$  (X-ray powder diffraction data). The alloy was synthesized by powder metallurgical reaction in an evacuated silica tube at 1073 K for 14 days.

Fig. 109. Yb–Mn–Ge, isothermal section at 670 K.

Dzianii (1995) reported on the existence of the  $\text{YbMn}_{0.52}\text{Ge}_2$  (2) compound:  $\text{CeNiSi}_2$  type,  $a=0.4071$ ,  $b=1.5503$ ,  $c=0.3964$  (X-ray powder diffraction).

One more ternary compound with an unknown structure was observed by Dzianii (1995) in the course of studying the phase equilibria in the Yb–Mn–Ge system at 670 K;  $\sim\text{Yb}_9\text{Mn}_{10}\text{Ge}_{10}$  (3).

Rossi et al. (1978b) investigated the crystal structure of the  $\text{YbMn}_2\text{Ge}_2$  compound by X-ray powder diffraction. The  $\text{CeGa}_2\text{Al}_2$ -type structure was announced for this phase with lattice parameters  $a=0.4067$ ,  $c=1.0871$ . For sample preparation, see  $\text{TbMn}_2\text{Ge}_2$  under Tb–Mn–Ge. Apparently this phase does not exist at 670 K.

#### 4.15.2. Yb–Fe–Ge

The phase diagram of the Yb–Fe–Ge system (fig. 110) was investigated by Dzianii (1995) by means of X-ray phase analysis of 90 samples. The alloys for investigation were prepared by arc melting. The samples were homogenized by annealing at 670 K for 480 hours. The purity of the starting components was Yb 99.8 mass%, Fe 99.9 mass%, and Ge 99.99 mass%. Five ternary compounds were observed.

$\text{YbFe}_6\text{Ge}_6$  (1) was found to crystallize with the  $\text{HfFe}_6\text{Ge}_6$ -type structure,  $a=0.5097$ ,  $c=0.8092$ , by Venturini et al. (1992) from X-ray powder diffraction data. The alloy was obtained by a powder metallurgical reaction in an evacuated silica tube at 1173 K for two weeks. At variance with these data,  $\text{YbFe}_6\text{Ge}_6$  was reported to be isotypic with the crystal structure of  $\text{YCo}_6\text{Ge}_6$  with lattice parameters  $a=0.5098$ ,  $c=0.4049$  (Dzianii et al. 1995a). The sample was prepared by arc melting the proper amounts of starting components followed by annealing at 670 K for two weeks.

$\text{YbFe}_4\text{Ge}_2$  (2) was found to crystallize with the  $\text{ZrFe}_4\text{Si}_2$  type structure,  $a=0.72279$ ,  $c=0.38764$ , by Dzianii et al. (1995b). For the experimental procedure, see Yb–Fe–Ge.

Fig. 110. Yb–Fe–Ge, isothermal section at 670 K.

According to X-ray powder diffraction data,  $\text{YbFe}_2\text{Ge}_2$  (3) is isostructural with the  $\text{CeGa}_2\text{Al}_2$  type, lattice parameters  $a=0.3924$ ,  $c=1.0503$  (Rossi et al. 1978a; X-ray powder diffraction).

Dzianii (1995) reported  $\text{Yb}(\text{Fe}_{0.43-0.25}\text{Ge}_{0.25-0.39})\text{Ge}_2$  (4) to crystallize with the  $\text{CeNiSi}_2$ -type structure ( $a=0.4070$ ,  $b=1.5475$ ,  $c=0.3961$ ; X-ray powder analysis).

One more ternary compound with an unknown structure was observed in the course of phase equilibrium studies of the ternary Yb–Fe–Ge system at 670 K by Dzianii (1995) employing X-ray powder diffraction:  $\sim\text{Yb}_9\text{Fe}_{10}\text{Ge}_{10}$  (5).

#### 4.15.3. Yb–Co–Ge

The isothermal section of the Yb–Co–Ge system at 670 K was derived by Dzianii et al. (1995c) (fig. 111) using X-ray analysis of 99 alloys prepared by arc melting the proper amounts of high-purity constituent elements. The melted buttons were then annealed in evacuated silica tubes for 500 hours. Seven ternary compounds were found to exist.

The crystal structure of the  $\text{YbCo}_6\text{Ge}_6$  (1) compound was reported by Buchholz and Schuster (1981):  $\text{YCo}_6\text{Ge}_6$  structure type,  $a=0.5078$ ,  $c=0.3910$ . The sample was melted under argon in a corundum crucible at 1073–1273 K.

$\text{YbCo}_4\text{Ge}_2$  (2) was found to adopt the  $\text{ZrFe}_4\text{Si}_2$ -type structure,  $a=0.7236$ ,  $c=0.3716$ , by Fedyna (1988) employing X-ray powder diffraction method. For sample preparation, see Pr–Fe–Ge.

The crystal structure of the  $\text{Yb}_3\text{Co}_4\text{Ge}_{13}$  (3) compound ( $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8705$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample which was prepared by heating a compacted mixture of the starting materials (Yb in pieces, 99.9 mass%; Co and Ge in powder, 99.99 mass%) in an evacuated quartz tube

Fig. 111. Yb–Co–Ge, isothermal section at 670 K.

at 1073 K. Bodak et al. (1987) reported the  $Y_3Co_4Ge_{13}$ -type structure for the  $Yb_3Co_4Ge_{13}$  compound ( $a=0.8725$ ; X-ray powder data) from an arc melted alloy annealed at 870 K.

$YbCo_2Ge_2$  (4) was found to adopt the  $CeGa_2Al_2$ -type structure,  $a=0.3996$ ,  $c=1.0123$  (Dzianii 1995; X-ray powder diffraction).

Méot-Meyer et al. (1985a) reported the crystal structure of  $YbCo_xGe_2$  (5),  $x=0.37$  ( $CeNiSi_2$  type,  $a=0.4077$ ,  $b=1.563$ ,  $c=0.3967$ ). The sample was prepared by a powder metallurgical reaction and annealed in an evacuated silica tube at 1173 K. Pecharsky et al. (1989) confirmed the formation and crystal structure of the  $YbCo_xGe_2$  compound from arc melted alloys annealed at 870 K ( $a=0.4045$ ,  $b=1.5512$ ,  $c=0.3948$ ; X-ray powder analysis).

In the course of phase diagram studies, two more ternary compounds with unknown structures were observed by Dzianii (1995):  $\sim YbCoGe$  (6) and  $\sim Yb_2CoGe_2$  (7).

$Yb_5Co_4Ge_{10}$  was observed to crystallize with the  $Sc_5Co_4Si_{10}$ -type structure by Méot-Meyer et al. (1985b). For experimental details, see  $YbCo_xGe_2$  under Yb–Co–Ge. Apparently this phase does not exist at 670 K.

#### 4.15.4. Yb–Ni–Ge

Figure 112 represents the isothermal section of the Yb–Ni–Ge system at 670 K, studied by Dzianii (1995). The isothermal section was constructed by means of X-ray powder analysis of 110 alloys which were arc melted and subsequently annealed in evacuated silica tubes for 480 h and finally quenched in water. The starting materials were Yb 99.8 mass%, Ni 99.9 mass%, and Ge 99.99 mass%.

Fig. 112. Yb–Ni–Ge, isothermal section at 670 K.

The ternary phase diagram is characterized by the existence of twelve ternary compounds and by the formation of substitutional solid solutions based at  $\text{Tm}_2\text{Ni}_{17}$  and  $\text{TmNi}_5$ , which dissolve 15 at.% Ge.

$\text{YbNi}_5\text{Ge}_3$  (1) was reported to crystallize with the  $\text{YNi}_5\text{Si}_3$ -type structure,  $a = 1.8892$ ,  $b = 0.3830$ ,  $c = 0.6779$ , by Fedyna et al. (1987). The arc melted alloy, annealed at 870 K, was investigated by X-ray powder diffraction analysis. The starting materials were Yb 99.8 mass%, Ni 99.99 mass%, and Ge 99.99 mass%.

$\text{Yb}_3\text{Ni}_{11}\text{Ge}_4$  (2) belongs to the  $\text{Sc}_3\text{Ni}_{11}\text{Si}_4$ -type structure group,  $a = 0.8259$ ,  $c = 0.8648$ , after Fedyna et al. (1987). The alloy was prepared in the same manner as  $\text{TmNi}_5\text{Ge}_3$ .

The  $\text{YbNi}_2\text{Ge}_2$  (4) compound was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a = 0.4001$ ,  $c = 0.9733$  (Rieger and Parthé 1969b).

$\text{YbNiGe}_3$  (5) with the  $\text{ScNiSi}_3$ -type structure ( $a = 0.4067$ ,  $b = 2.1548$ ,  $c = 0.4067$ , X-ray powder diffraction analysis) was reported by Dzianii (1995). For the details of sample preparation and the purity of starting materials, see Yb–Ni–Ge.

$\text{Yb}_2\text{NiGe}_6$  (6) has been found by Dzianii (1995) from X-ray powder diffraction to be isostructural with  $\text{Ce}_2\text{CuGe}_6$  ( $a = 0.3948$ ,  $b = 2.100$ ,  $c = 0.3960$ ). The sample was prepared by arc melting ingots of the constituting elements and annealing the resulting button at 670 K for 480 h. For the purity of starting materials, see Yb–Ni–Ge.

Gorelenko et al. (1984) investigated the crystal structure of  $\text{YbNiGe}$  (9) (TiNiSi type,  $a = 0.6740$ ,  $b = 0.4162$ ,  $c = 0.7217$ ; X-ray powder analysis). The proper amounts of starting materials were arc melted, and the resulting alloy was annealed in an evacuated quartz tube at 870 K for 350 hours.

$\text{YbNi}_{0.6}\text{Ge}_{1.4}$  (12) was said to adopt the  $\text{AlB}_2$ -type structure,  $a = 0.4193$ ,  $c = 0.3965$  (Contardi et al. 1977; X-ray powder diffraction). Dzianii (1995) observed a homogeneity field for the compound with  $\text{AlB}_2$  structure and obtained significantly different lattice parameters:  $\text{Yb}_2(\text{Ni}, \text{Ge})_3$ ,  $a = 0.3405\text{--}0.3764$ ,  $c = 0.3942\text{--}0.4009$  (X-ray powder diffraction).

Five more ternary compounds with unknown structure were observed by Dzianii (1995) in the Yb–Ni–Ge system:  $\sim\text{Yb}_{0.17}\text{Ni}_{0.53}\text{Ge}_{0.30}$  (3),  $\sim\text{Yb}_{0.25}\text{Ni}_{0.25}\text{Ge}_{0.50}$  (7),  $\sim\text{Yb}_{0.27}\text{Ni}_{0.28}\text{Ge}_{0.45}$  (8),  $\sim\text{Yb}_{0.33}\text{Ni}_{0.27}\text{Ge}_{0.40}$  (10),  $\sim\text{Yb}_{0.33}\text{Ni}_{0.17}\text{Ge}_{0.50}$  (11).

#### 4.15.5. Yb–Cu–Ge

The isothermal section for the ternary Yb–Cu–Ge system over the whole concentration region (fig. 113) was established by Salamakha et al. (1996a). Four ternary compounds were observed and characterized by employing X-ray powder analysis of arc melted alloys annealed at 670 K. The starting materials were used in the form of ingots of high-purity elements: Yb 99.9 mass%, Cu 99.99 mass%, and Ge 99.999 mass%.

Iandelli (1993) observed  $\text{YbCuGe}$  (4) with the  $\text{CaIn}_2$ -type structure ( $a = 0.4213$ ,  $c = 0.7036$ , X-ray powder analysis). The alloy was prepared from filings or powders of the metals (Yb 99.7 mass%, Cu and Ge 99.99 mass%), which were mixed, sealed in a tantalum crucible under argon, melted by induction heating, and annealed for 10 days at

Fig. 113. Yb–Cu–Ge, isothermal section at 670 K.

1023 K. The crystal structure of this compound was confirmed by Dzianii et al. (1995d),  $a=0.4186$ ,  $c=0.6988$ . For the experimental details, see the preceding paragraph.

$\text{Yb}_6\text{Cu}_8\text{Ge}_8$  (3) crystallizes with the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$ -type structure, lattice parameters  $a=1.371$ ,  $b=0.659$ ,  $c=0.413$  (Hanel and Nowotny 1970). The crystal structure was confirmed for the  $\text{Yb}_6\text{Cu}_8\text{Ge}_8$  compound by Dzianii (1995) from X-ray powder diffraction data,  $a=1.414$ ,  $b=0.6637$ ,  $c=0.4201$ .

Konyk et al. (1988) investigated the crystal structure of  $\text{Yb}_2\text{CuGe}_6$  (2), which was prepared by arc melting under argon and annealing at 870 K in an evacuated quartz tube for 720 h. From X-ray powder analysis, the  $\text{Ce}_2\text{CuGe}_6$ -type structure was claimed,  $a=0.3994$ ,  $b=0.4082$ ,  $c=2.1018$ .

Rieger and Parthé (1969b) prepared  $\text{YbCu}_2\text{Ge}_2$  (1) with the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a=0.4045$ ,  $c=1.0228$ .

#### 4.15.6. Yb–Nb–Ge

The phase diagram of the Yb–Nb–Ge system has not been established yet. However, the existence of a compound  $\text{Yb}_2\text{Nb}_3\text{Ge}_4$  with the  $\text{Ce}_2\text{Sc}_3\text{Si}_4$ -type structure ( $a=0.6937$ ,  $b=1.3449$ ,  $c=0.7109$ ) was reported by Le Bihan et al. (1996a) from X-ray powder diffraction data of an arc melted alloy. The starting materials were: Yb and Nb 99.99 mass%, Ge 99.999 mass%.

#### 4.15.7. Yb–Ru–Ge

X-ray powder analysis of an alloy of the  $\text{YbRu}_2\text{Ge}_2$  composition indicated that it had the  $\text{CeGa}_2\text{Al}_2$ -type structure with  $a=0.4203$ ,  $c=0.9763$  (Francois et al. 1985). The sample

was obtained by a powder metallurgical reaction at 1273 K. The starting components were Yb (3N), Ru (4N), and Ge (4N).

Yb<sub>3</sub>Rh<sub>4</sub>Sn<sub>13</sub>-type structure was reported for the Yb<sub>3</sub>Ru<sub>4</sub>Ge<sub>13</sub> compound ( $a=0.8911$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days. The starting materials were Yb (3N), Ru (3N), and Ge (6N).

#### 4.15.8. Yb–Rh–Ge

Venturini et al. (1985b) reported an X-ray powder diffraction study of the Yb<sub>3</sub>Rh<sub>4</sub>Ge<sub>13</sub> compound from a sample which was prepared by heating a mixture of the starting components (Yb 3N, Rh 4N, Ge 4N) in an evacuated quartz tube at 1073 K. The crystal structure was found to be of the Yb<sub>3</sub>Rh<sub>4</sub>Sn<sub>13</sub> type,  $a=0.8941$ .

Francois et al. (1985) determined the CeGa<sub>2</sub>Al<sub>2</sub>-type structure for the YbRh<sub>2</sub>Ge<sub>2</sub> compound,  $a=0.4062$ ,  $c=1.0065$ .

Venturini et al. (1984) established the existence of the Yb<sub>5</sub>Rh<sub>4</sub>Ge<sub>10</sub> compound with Sc<sub>5</sub>Co<sub>4</sub>Si<sub>10</sub>-type structure and lattice parameters  $a=1.2886$ ,  $c=0.4234$  from X-ray powder analysis of a sample obtained by heating a mixture of powders in an evacuated tube at 1073 K.

Yb<sub>4</sub>Rh<sub>7</sub>Ge<sub>6</sub> belongs to the U<sub>4</sub>Re<sub>7</sub>Si<sub>6</sub>-type structure family,  $a=0.8254$ , according to Francois et al. 1985 (X-ray powder diffraction). The alloy was synthesized by heating a mixture of powders of the constituent elements in an evacuated quartz tube at 1273 K. Starting components were Yb (3N), Rh (4N), and Ge (4N).

#### 4.15.9. Yb–Pd–Ge

A systematic study of the Yb–Pd–Ge system (fig. 114) has been performed by Seropegin et al. (1994) employing X-ray phase analysis, microstructural and local X-ray spectral analyses of 152 samples which were arc melted and annealed at 870 K for 600 h. The existence of one ternary compound was confirmed and formation of nine other ternary phases was observed for the first time. The purity of the metals used for the synthesis of the alloys was Yb 99.98 mass%, Pd and Ge 99.99 mass%.

According to X-ray powder diffraction analysis, YbPd<sub>2</sub>Ge<sub>2</sub> (3) was reported to adopt the CeGa<sub>2</sub>Al<sub>2</sub>-type structure,  $a=0.4287$ ,  $c=1.0020$  (Rossi et al. 1979). Seropegin et al. (1994) confirmed the existence and structure of this compound with  $a=0.42841$ ,  $c=1.0001$ .

Seropegin et al. (1994) reported an X-ray powder analysis of the Yb<sub>2</sub>PdGe<sub>6</sub> (4) compound which was found to crystallize with the Ce<sub>2</sub>CuGe<sub>6</sub>-type structure,  $a=0.3974$ ,  $b=2.1834$ ,  $c=0.40689$ . For the experimental procedure, see the Yb–Pd–Ge isothermal section. Sologub et al. (1995a) confirmed the formation of Yb<sub>2</sub>PdGe<sub>6</sub> with the Ce<sub>2</sub>CuGe<sub>6</sub>-type structure and obtained  $a=0.40755$ ,  $b=0.39934$ ,  $c=2.1851$ . For the experimental procedure, see La<sub>2</sub>PdGe<sub>6</sub> under La–Pd–Ge. The starting materials used were of purity 99.9 mass%.

Fig. 114. Yb-Pd-Ge, isothermal section at 870 K.

In the course of the phase equilibria investigation, three more compounds were observed and characterized:  $\text{YbPdGe}_2$  (5),  $\text{NdIrGe}_2$  type,  $a = 0.4336$ ,  $b = 0.8626$ ,  $c = 1.6071$  (X-ray powder diffraction);  $\text{YbPd}_{0.5-0.62}\text{Ge}_{1.5-1.38}$  (7),  $\text{AlB}_2$  type,  $a = 0.42276-0.42263$ ,  $c = 0.40686-0.40649$  (X-ray powder diffraction);  $\text{YbPdGe}$  (9),  $\text{KHg}_2$  type,  $a = 0.4344$ ,  $b = 0.6839$ ,  $c = 0.7522$  (X-ray powder diffraction).

The crystal structures of the compounds  $\sim\text{Yb}_{10}\text{Pd}_{75}\text{Ge}_{15}$  (1) (Seropegin et al. 1994),  $\sim\text{Yb}_{20}\text{Pd}_{20}\text{Ge}_{60}$  (2) (Seropegin et al. 1994),  $\sim\text{YbPd}_2\text{Ge}$  (6) (Jorda et al. 1983),  $\sim\text{Yb}_{33.3}\text{Pd}_{28}\text{Ge}_{38.7}$  (8) (Seropegin et al. 1994) and  $\sim\text{Yb}_{42}\text{Pd}_{13}\text{Ge}_{45}$  (10) (Seropegin et al. 1994) have not been determined.

#### 4.15.10. Yb-Ag-Ge

No ternary phase diagram has been established for the Yb-Ag-Ge system, however one ternary compound has been characterized. Gibson et al. (1996) reported an X-ray powder investigation of the  $\text{YbAgGe}$  compound. It was found to adopt the  $\text{ZrNiAl}$ -type structure,  $a = 0.70524$ ,  $c = 0.41387$ . The sample was arc melted and annealed at 970 K for ten days.

#### 4.15.11. Yb-Os-Ge

No phase diagram is available for the ternary Yb-Os-Ge system, but two ternary compounds have been observed.

$\text{Yb}_4\text{Os}_7\text{Ge}_6$  belongs to the  $\text{U}_4\text{Re}_7\text{Si}_6$ -type structure family,  $a = 0.8288$  (Francois et al. 1985; X-ray powder diffraction). The alloy was synthesized by heating a mixture of powders of the constituent elements in an evacuated quartz tube at 1273 K. The starting components were Yb (3N), Os (4N), and Ge (4N).

The  $\text{Pr}_3\text{Rh}_4\text{Sn}_{13}$ -type structure was announced for the  $\text{Yb}_3\text{Os}_4\text{Ge}_{13}$  compound ( $a = 0.8941$ ) by Segre et al. (1981a) from X-ray powder analysis of an arc melted sample annealed at 1523 K for 1 day and at 1273 K for 7 days sample. The starting materials were Yb (3N), Os (3N), and Ge (6N).

#### 4.15.12. *Yb-Ir-Ge*

No ternary phase diagram has been established for the Yb-Ir-Ge system, however three ternary compounds have been characterized.

Méot-Meyer et al. (1985b) observed the  $\text{Yb}_5\text{Ir}_4\text{Ge}_{10}$  compound with  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ -type structure from a sample which was obtained by heating a compacted mixture of powders in evacuated tube at 1073 K. No lattice parameters were given.

Venturini et al. (1985b) reported an X-ray powder diffraction study of the  $\text{Yb}_3\text{Ir}_4\text{Ge}_{13}$  compound from a sample which was prepared from the pure components (Yb 3N, Ir 4N, Ge 4N) by a powder metallurgical reaction at 1073 K. The crystal structure was found to be of the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a = 0.8936$ .

$\text{Yb}_4\text{Ir}_7\text{Ge}_6$  was reported to adopt  $\text{U}_4\text{Re}_7\text{Si}_6$ -type structure ( $a = 0.8262$ ; Francois et al. 1985) from a sample which was obtained by heating a mixture of powders of the starting materials (Yb 3N, Ir 4N, Ge 4N) in an evacuated quartz tube at 1273 K.

#### 4.15.13. *Yb-Pt-Ge*

A systematic study of the Yb-Pt-Ge system (fig. 115) has been performed by Borisenko (1993) employing X-ray phase analysis as well as microstructural and local X-ray spectral analyses of 72 samples which were arc melted and annealed at 870 K for 600 h. The

Fig. 115. Yb-Pt-Ge, isothermal section at 870 K.

existence of three ternary compounds was observed. The purity of the metals used for the synthesis of the alloys was Yb 99.98 mass%, Pt and Ge 99.99 mass%.

Borisenko (1993) reported an X-ray powder analysis of the  $\text{Yb}_2\text{PtGe}_6$  (1) compound which was found to crystallize with the  $\text{Ce}_2\text{CuGe}_6$ -type structure,  $a=0.3949$ ,  $b=2.186$ ,  $c=0.4091$ . For the experimental procedure, see the preceding paragraph. Sologub et al. (1995a) confirmed the formation of  $\text{Yb}_2\text{PtGe}_6$  with the  $\text{Ce}_2\text{CuGe}_6$ -type structure and obtained  $a=0.40482$ ,  $b=0.39771$ ,  $c=2.1940$ . For the experimental procedure, see  $\text{La}_2\text{PdGe}_6$  under La–Pd–Ge. The purity of the starting materials used was 99.9 mass%.

In the course of phase equilibrium studies, two more compounds were observed and characterized by X-ray powder diffraction:  $\text{YbPtGe}_2$  (2),  $\text{NdIrGe}_2$  type,  $a=0.4337$ ,  $b=0.8734$ ,  $c=1.6134$ ; and  $\text{YbPtGe}$  (3),  $\text{TiNiSi}$  type,  $a=0.6897$ ,  $b=0.4325$ ,  $c=0.7542$ .

#### 4.15.14. *Yb–Au–Ge*

Only one report exists on the interaction of components in the ternary Yb–Au–Ge system: Rossi et al. (1992) observed and characterized the  $\text{YbAuGe}$  compound as having the  $\text{LiGaGe}$ -type structure with lattice parameters  $a=0.4475$ ,  $c=0.7163$  (X-ray powder diffraction). The sample was obtained by melting the metals in an induction furnace and annealing at 1070 K for one week. The metals used had a purity of around 99.9 mass.% for Yb and 99.99 mass.% for Au and Ge.

#### 4.16. *Lu–d element–Ge systems*

##### 4.16.1. *Lu–Mn–Ge*

No ternary phase diagram for the Lu–Mn–Ge system is available. Three ternary compounds have been reported for various lutetium–manganese–germanium combinations.

$\text{LuMn}_6\text{Ge}_6$  was found to crystallize in the  $\text{HfFe}_6\text{Ge}_6$ -type structure by Venturini et al. (1992),  $a=0.5211$ ,  $c=0.8134$  (X-ray powder diffraction data). The alloy was synthesized by a powder metallurgical reaction in an evacuated silica tube at 1073 K for 14 days.

$\text{LuMn}_{0.27-0.12}\text{Ge}_2$  was found by Francois et al. (1990) to adopt the  $\text{CeNiSi}_2$ -type structure with lattice parameters  $a=0.4053-0.4028$ ,  $b=1.543-1.558$ ,  $c=0.3956-0.3897$  (X-ray powder diffraction data). For sample preparation, see  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$  under Gd–Fe–Ge.

Meyer et al. (1983) investigated the crystal structure of the  $\text{LuMnGe}_2$  compound, and found it had a new structure type,  $a=0.5466$ ,  $b=1.8519$ ,  $c=0.8173$  (X-ray single-crystal method) from an alloy obtained by heating the proper amounts of the metals in a quartz tube under argon and annealing at 1173 K.

##### 4.16.2. *Lu–Fe–Ge*

No phase diagram has been constructed for the Lu–Fe–Ge system; six ternary compounds have been found and characterized by different groups of authors.

$\text{LuFe}_6\text{Ge}_6$  was reported to be isotypic with  $\text{YCo}_6\text{Ge}_6$ , lattice parameters  $a=0.5087$ ,  $c=0.4034$  (Mruz et al. 1984). The sample was prepared by arc melting the proper amounts

of the starting components followed by annealing at 870 K for two weeks. At variance with these data,  $\text{LuFe}_6\text{Ge}_6$  was found to crystallize with the  $\text{HfFe}_6\text{Ge}_6$ -type structure,  $a=0.5096$ ,  $c=0.8081$ , by Venturini et al. (1992) from X-ray powder diffraction data. The alloy was obtained by a powder metallurgical reaction in an evacuated silica tube at 1173 K for two weeks.

Pecharsky et al. (1989) reported  $\text{LuFe}_x\text{Ge}_2$  to crystallize with the  $\text{CeNiSi}_2$ -type structure ( $a=0.4042$ ,  $b=1.5431$ ,  $c=0.3947$ ; X-ray powder analysis). The alloy was arc melted and annealed at 870 K. The purity of the starting materials was greater than 99.9 mass%. Francois et al. (1990) confirmed the structure of this compound and established the composition as  $\text{LuFe}_{0.33-0.11}\text{Ge}_2$ ,  $a=0.4121$ ,  $b=1.581$ ,  $c=0.4011$  (X-ray powder diffraction data). For sample preparation, see  $\text{GdFe}_{0.25-0.46}\text{Ge}_2$  under Gd–Fe–Ge.

$\text{LuFe}_4\text{Ge}_2$  is isotopic with  $\text{ZrFe}_4\text{Si}_2$ , lattice parameters  $a=0.7200$ ,  $c=0.3854$ , after Fedyna (1988). The alloy was prepared by arc melting the proper amounts of the starting components followed by annealing at 870 K for 400 hours.

Oleksyn (1990) investigated the crystal structure of the  $\text{Lu}_{117}\text{Fe}_{52}\text{Ge}_{112}$  compound by the X-ray powder method ( $\text{Tb}_{117}\text{Fe}_{52}\text{Ge}_{112}$  type,  $a=2.792$ ). The alloy was synthesized by arc melting and annealing at 1070 K for 350 h. The starting materials were Lu 99.83 mass%, Fe 99.9 mass%, and Ge 99.99 mass%.

$\text{Lu}_6\text{Fe}_8\text{Ge}_8$  belongs to the  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$ -type structure family,  $a=1.3280$ ,  $b=0.6805$ ,  $c=0.4038$  (X-ray powder diffraction; Fedyna et al. 1994).

Fedyna and Zavodnik (1988) reported a single-crystal investigation of the  $\text{Lu}_3\text{Fe}_2\text{Ge}_3$  compound, showing that it had the  $\text{Hf}_3\text{Ni}_2\text{Si}_3$ -type structure,  $a=0.41272$ ,  $b=1.047$ ,  $c=1.3611$ . The single crystal was isolated from an arc melted alloy.

#### 4.16.3. Lu–Co–Ge

The phase diagram of the Lu–Co–Ge system has not yet been established; seven ternary compounds have been identified and characterized for various lutetium–cobalt–germanium combinations.

Méot-Meyer et al. (1985a) reported that  $\text{LuCo}_{1-x}\text{Ge}_2$ ,  $x=0.34$ , has the  $\text{CeNiSi}_2$ -type structure with  $a=0.4038$ ,  $b=1.554$ ,  $c=0.3939$ . The sample was prepared by a powder metallurgical reaction and annealed in an evacuated silica tube at 1173 K. Pecharsky et al. (1989) also investigated the formation and crystal structure of the  $\text{LuCo}_{1-x}\text{Ge}_2$  compound by X-ray powder analysis of an arc melted alloy annealed at 870 K:  $\text{CeNiSi}_2$  type,  $a=0.4038-0.4040$ ,  $b=1.5512-1.5551$ ,  $c=0.3948-0.3949$ .

The crystal structure of  $\text{Lu}_3\text{Co}_4\text{Ge}_{13}$  ( $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type,  $a=0.8700$ ; X-ray powder diffraction) was investigated by Venturini et al. (1985b) from a sample which was prepared by heating a compacted mixture of the starting materials (Lu in pieces, 99.9 mass%; Co and Ge in powder, 99.99 mass%) in an evacuated quartz tube at 1073 K. Bodak et al. (1987) reported the  $\text{Y}_3\text{Co}_4\text{Ge}_{13}$  type for the  $\text{Lu}_3\text{Co}_4\text{Ge}_{13}$  compound ( $a=0.8694$ ; X-ray powder data) from an arc melted alloy annealed at 870 K.

Gorelenko et al. (1984) reported the crystal structure of LuCoGe (TiNiSi type,  $a = 0.6720$ ,  $b = 0.4140$ ,  $c = 0.7226$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours.

$\text{Lu}_2\text{CoGe}_6$  is isotypic with  $\text{Ce}_2\text{CuGe}_6$ ,  $a = 0.3904$ ,  $b = 0.3936$ ,  $c = 2.1192$  (Oleksyn et al. 1991; X-ray powder diffraction data). The sample was melted in an arc furnace and annealed at 1070 K in evacuated quartz capsule for 400 h. The purity of the starting materials was greater than 99.9 mass%.

Koterlyn (1996) investigated the crystal structure of the  $\text{LuCo}_{3.8}\text{Ge}_{1.2}$  compound which belongs to the  $\text{CaCu}_5$ -type structure,  $a = 0.48823$ ,  $c = 0.40301$  (X-ray powder diffraction).

Bodak et al. (1986) reported the crystal structure for  $\text{Lu}_2\text{CoGe}_2$  ( $\text{Sc}_2\text{CoSi}_2$  type,  $a = 1.0234$ ,  $b = 1.0049$ ,  $c = 0.4109$ ,  $\gamma = 117.31^\circ$ ; X-ray powder diffraction) from an arc melted sample annealed at 870 K.

$\text{LuCo}_4\text{Ge}_2$  is isotypic with  $\text{ZrFe}_4\text{Si}_2$ , lattice parameters  $a = 0.7199$ ,  $c = 0.3735$ , after Fedyna (1988). The alloy was prepared by arc melting the proper amounts of the starting components and annealing at 870 K for 400 hours.

#### 4.16.4. Lu–Ni–Ge

No isothermal section for the Lu–Ni–Ge system is available; eight ternary compounds were observed and characterized by different groups of authors.

$\text{LuNi}_5\text{Ge}_3$  was reported to crystallize with the  $\text{YNi}_5\text{Si}_3$ -type structure,  $a = 1.8973$ ,  $b = 0.3826$ ,  $c = 0.6775$ , by Fedyna et al. (1987). An arc melted alloy, annealed at 870 K, was investigated by X-ray powder diffraction analysis. The starting materials were Lu 99.83 mass%, Ni 99.99 mass%, and Ge 99.99 mass%.

$\text{Lu}_3\text{Ni}_{11}\text{Ge}_4$  belongs to the  $\text{Sc}_3\text{Ni}_{11}\text{Si}_3$ -type structure,  $a = 0.8249$ ,  $c = 0.8641$ , after Fedyna et al. (1987). For sample preparation, see the preceding paragraph.

The  $\text{LuNi}_2\text{Ge}_2$  compound was found to adopt the  $\text{CeGa}_2\text{Al}_2$ -type structure,  $a = 0.39975$ ,  $c = 0.97538$  (Bodak and Koterlyn 1995).

$\text{LuNiGe}_3$  with the  $\text{SmNiGe}_3$ -type structure ( $a = 2.1305$ ,  $b = 0.3932$ ,  $c = 0.3982$ , X-ray powder diffraction analysis) was reported by Bodak et al. (1985). For the details of sample preparation and the purity of the starting materials, see  $\text{LuNi}_5\text{Ge}_3$ .

$\text{Lu}_2\text{NiGe}_6$  has been found by Oleksyn (1990) from X-ray powder diffraction to be isostructural with  $\text{Ce}_2\text{CuGe}_6$  ( $a = 0.3908$ ,  $b = 0.4007$ ,  $c = 2.1265$ ). The sample was prepared by arc melting ingots of the constituting elements and annealing at 1070 K for 700 h. For the purity of starting materials, see  $\text{LuNi}_5\text{Ge}_3$ .

Pecharsky et al. (1989) investigated the formation and crystal structure of the  $\text{LuNi}_{1-x}\text{Ge}_2$  compound by X-ray powder analysis of an arc melted alloy annealed at 870 K ( $\text{CeNiSi}_2$  type,  $a = 0.3993\text{--}0.4045$ ,  $b = 1.5566\text{--}1.5690$ ,  $c = 0.3852\text{--}0.3929$ ). For sample preparation, see  $\text{LuFe}_{1-x}\text{Ge}_2$  under Lu–Fe–Ge. Francois et al. (1990) confirmed the structure and reported the composition and lattice parameters  $\text{LuNi}_{0.48\text{--}0.19}\text{Ge}_2$ ,  $a = 0.4037\text{--}0.4015$ ,  $b = 1.535\text{--}1.558$ ,  $c = 0.3945\text{--}0.3898$  (X-ray powder diffraction) from a sample obtained by a powder metallurgical reaction at 1173 K.

Gorelenko et al. (1984) reported the crystal structure of LuNiGe (TiNiSi type,  $a = 0.6727$ ,  $b = 0.4147$ ,  $c = 0.7229$ ; X-ray powder analysis). The alloy was obtained by arc melting and annealing in an evacuated quartz tube at 870 K for 350 hours. Koterlyn et al. (1994) investigated a single crystal which was extracted from an arc melted LuNiGe alloy. A new structure type was observed,  $a = 0.4116$ ,  $b = 0.9194$ ,  $c = 2.2334$ . According to DTA, this phase exists above 1570 K.

Oleksyn (1990) reported on the crystal structure of LuNiGe<sub>2</sub> from X-ray powder diffraction (NdIrGe<sub>2</sub> type,  $a = 0.4082$ ,  $b = 0.8893$ ,  $c = 1.5795$ ). The proper amounts of the starting components were arc melted and annealed at 1070 K.

#### 4.16.5. Lu–Cu–Ge

No isothermal section is available for the Lu–Cu–Ge system; four ternary compounds have been found and analyzed by various groups of authors.

Rieger and Parthé (1969a) investigated the occurrence of the AlB<sub>2</sub>-type structure by means of X-ray powder diffraction of arc melted alloys. The data presented indicated a compound of LuCu<sub>0.67</sub>Ge<sub>1.33</sub> stoichiometry with  $a = 0.383$ ,  $c = 0.405$ .

Iandelli (1993) observed LuCuGe with the CaIn<sub>2</sub> type ( $a = 0.4212$ ,  $c = 0.6962$ , X-ray powder analysis). The alloy was prepared from turnings or powders of the metals (lutetium 99.7 mass%, copper and germanium 99.99 mass%), which were mixed and sealed in a tantalum crucible under argon, melted by induction heating, and annealed for 10 days at 1023 K.

Lu<sub>6</sub>Cu<sub>8</sub>Ge<sub>8</sub> crystallizes with the Gd<sub>6</sub>Cu<sub>8</sub>Ge<sub>8</sub>-type structure, lattice parameters  $a = 1.3661$ ,  $b = 0.6581$ ,  $c = 0.4113$  (Rieger 1970).

Francois et al. (1990) observed the CeNiSi<sub>2</sub>-type structure for the LuCu<sub>0.14</sub>Ge<sub>2</sub> compound and reported lattice parameters  $a = 0.4029$ ,  $b = 1.567$ ,  $c = 0.3903$  (X-ray powder diffraction) from a sample obtained by a powder metallurgical reaction at 1173 K.

#### 4.16.6. Lu–Nb–Ge

The phase diagram of the Lu–Nb–Ge system has not been established yet. The existence of the compound Lu<sub>2</sub>Nb<sub>3</sub>Ge<sub>4</sub> with the Ce<sub>2</sub>Sc<sub>3</sub>Si<sub>4</sub>-type structure ( $a = 0.6895$ ,  $b = 1.3392$ ,  $c = 0.7071$ ) was reported by Le Bihan et al. (1996a) from X-ray powder diffraction data of an arc melted alloy. The starting materials were: Lu and Nb 99.99 mass%, Ge 99.999 mass%.

#### 4.16.7. Lu–Mo–Ge

The existence of Lu<sub>2</sub>Mo<sub>3</sub>Ge<sub>4</sub> with the Ce<sub>2</sub>Sc<sub>3</sub>Si<sub>4</sub>-type structure ( $a = 0.6789$ ,  $b = 1.3012$ ,  $c = 0.6990$ ) was reported by Le Bihan et al. (1996b). For sample preparation and purity of starting materials, see Lu–Nb–Ge.

Table 29  
Crystallographic data for the ternary Lu–Ru(Rh,Pd)–Ge compounds

Compound	Structure	Lattice parameters (nm)			Reference
		<i>a</i>	<i>b</i>	<i>c</i>

#### 4.16.8. Lu–Ru(Rh, Pd)–Ge

The ternary Lu–Ru(Rh, Pd)–Ge systems have been studied only with respect to the formation of compounds with specific compositions and structures. Their crystallographic characteristics are listed in table 29.

#### 4.16.9. Lu–Ag–Ge

Protsyk (1994) constructed the equilibrium phase diagram for the Lu–Ag–Ge system at 770 K (fig. 116) by means of X-ray powder phase analysis of 65 alloys. The samples

Fig. 116. Lu–Ag–Ge, isothermal section at 770 K.

were arc melted and annealed for 500 h. Two ternary compounds were observed.  $\text{LuAg}_2$  dissolves 20 at.% Ge.

The crystal structure of the  $\text{LuAgGe}$  (1) compound was investigated by Protsyk (1994) by X-ray powder diffraction method. It was found to adopt the  $\text{ZrNiAl}$ -type structure with lattice parameters  $a=0.7006$ ,  $c=0.4129$ . The crystal structure was confirmed by Gibson et al. (1996), with lattice parameters  $a=0.71025$ ,  $c=0.41337$  (X-ray powder diffraction).

The crystal structure of  $\sim\text{Lu}_5(\text{Ag,Ge})_4$  (2) was not resolved (Protsyk 1994).

#### 4.16.10. *Lu–Re–Ge*

The only information on the system  $\text{Lu–Re–Ge}$  is due to Francois et al. (1990) who investigated the occurrence of the compound with a  $\text{CeNiSi}_2$  type; no phase diagram is available.

$\text{LuRe}_{0.12}\text{Ge}_2$  was found by Francois et al. (1990) to crystallize with the  $\text{CeNiSi}_2$ -type structure with lattice parameters  $a=0.4085$ ,  $b=1.551$ ,  $c=0.3991$  (X-ray powder diffraction data). The alloy was prepared from a mixture of the proper amounts of the components with purity of 99.9 mass% by a metallurgical reaction in a quartz tube at 1173 K.

#### 4.16.11. *Lu–Os(Ir)–Ge*

The ternary  $\text{Lu–Os(Ir)–Ge}$  systems have been studied only with respect to the formation of compounds with specific compositions and structures. Their crystallographic characteristics are listed in table 30.

Table 30  
Crystallographic data for the ternary  $\text{Lu–Os(Ir,Pt)–Ge}$  compounds

Compound	Structure	Lattice parameters (nm)			Reference
		<i>a</i>	<i>b</i>	<i>c</i>	
$\text{LuOsGe}_2$	$\text{TiMnSi}_2$	0.951	1.048	0.827	Venturini et al. (1985a)
$\text{Lu}_3\text{Os}_4\text{Ge}_{13}$	$\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$	0.8941			Segre et al. (1981a)
$\text{Lu}_4\text{Os}_7\text{Ge}_6$	$\text{U}_4\text{Re}_7\text{Si}_6$	0.8276			Francois et al. (1985)
$\text{Lu}_4\text{Ir}_7\text{Ge}_6$	$\text{U}_4\text{Re}_7\text{Si}_6$	0.8258			Francois et al. (1985)
$\text{Lu}_5\text{Ir}_4\text{Ge}_{10}$	$\text{Sc}_5\text{Co}_4\text{Si}_{10}$				Méot-Meyer et al. (1985b)
$\text{Lu}_3\text{Ir}_4\text{Ge}_{13}$	$\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$	0.8898			Venturini et al. (1985b)

#### 4.16.12. *Lu–Au–Ge*

No ternary phase diagram exists for the  $\text{Lu–Au–Ge}$  system, however, a ternary compound of lutetium with gold and germanium in the stoichiometric ratio 1:1:1 has been identified and studied by means of X-ray analysis by Pöttgen et al. (1996a).  $\text{LuAuGe}$  was found to adopt the  $\text{LiGaGe}$  type with lattice parameters  $a=0.43775$ ,  $c=0.71138$ . The sample was prepared by melting a mixture of the metals in an arc furnace and annealing at 1070 K.

## 5. Rare earth–f element–germanium systems

### 5.1. Sc–R'–Ge systems

#### 5.1.1. Sc–Y–Ge

The phase equilibria in the Sc–Y–Ge system (fig. 117) were investigated by Shpyrka and Mokra (1991) by means of X-ray phase and microstructural analyses of alloys which were arc melted and subsequently annealed in evacuated silica tubes for 350 h at 870 K and finally quenched in water. The starting materials were Sc 99.92 mass%, Y 99.90 mass%, and Ge 99.99 mass%. The phase relations are characterized by the existence of three ternary compounds and the formation of a continuous solid solution (Sc, Y)<sub>5</sub>Ge<sub>3</sub> originating at the isotypic binary compounds. The binary compounds ScGe<sub>2</sub>, Y<sub>2</sub>Ge<sub>3</sub> and Sc<sub>11</sub>Ge<sub>10</sub> dissolve 18, 10 and 8 at.% of third component, respectively.

Fig. 117. Sc–Y–Ge, isothermal section at 870 K.

In the course of a phase equilibrium study, three ternary compounds were observed by Shpyrka and Mokra (1991): Sc<sub>2.7</sub>Y<sub>2.3</sub>Ge<sub>4</sub> (1) was found to be isotypic with Sm<sub>5</sub>Ge<sub>4</sub>,  $a = 0.7283$ ,  $b = 1.418$ ,  $c = 0.7461$ ; Sc<sub>1.35</sub>Y<sub>3.65</sub>Ge<sub>4</sub> (3) belongs to the Sm<sub>5</sub>Ge<sub>4</sub>-type structure family,  $a = 0.7440$ ,  $b = 1.431$ ,  $c = 0.7578$ ; and  $\sim$ Sc<sub>0.3</sub>Y<sub>0.7</sub>Ge<sub>2</sub> (2) crystallizes with an unknown structure type.

#### 5.1.2. Sc–La–Ge

No phase diagram is available for the Sc–La–Ge system; however two ternary compounds were observed and characterized in the course of searching for isostructural series of compounds.

Sc<sub>3</sub>La<sub>1.22</sub>Ge<sub>4</sub> was found to be isotypic with Sc<sub>3</sub>Ce<sub>2</sub>Si<sub>4</sub>,  $a = 0.7252$ ,  $b = 1.4350$ ,  $c = 0.7652$  (X-ray powder diffraction; Shpyrka et al. 1990). ScLaGe belongs to the

ScCeSi type,  $a=0.4351$ ,  $c=1.6067$  (X-ray powder diffraction; Shpyrka 1990). For the experimental details, see Sc–Y–Ge.

Shpyrka (1990) investigated the phase formation in the section ScGe<sub>2</sub>–LaGe<sub>2</sub>, and no ternary compounds were observed.

### 5.1.3. Sc–Ce–Ge

Phase relations in the isothermal section of the Sc–Ce–Ge system at 870 K (fig. 118) were determined by Bodak and Kokhan (1983) from X-ray powder diffraction and microstructural analyses of 120 alloys prepared by arc melting Sc (99.92 mass%), Ce (99.56 mass%) and Ge (99.99 mass%) ingots. The melted buttons were then annealed at 870 K for 400 h in evacuated silica tubes. Four ternary compounds were found to exist. Up to 4 at.% Sc and 8 at.% Sc dissolve in CeGe<sub>2-1.78</sub> and CeGe<sub>1.6-1.56</sub>. The solubilities of third component in other binary compounds were reported to be negligible.

The crystal structures of Sc<sub>3</sub>Ce<sub>1.22</sub>Ge<sub>4</sub> (2) (Sc<sub>3</sub>Ce<sub>2</sub>Si<sub>4</sub> type;  $a=0.7188$ ,  $b=1.339$ ,  $c=0.7416$ ) and ScCeGe (3) (ScCeSi type;  $a=0.4314$ ,  $c=1.5913$ ) were investigated by Shpyrka et al. (1990) and Shpyrka (1990), respectively, employing an X-ray single-crystal method. The samples were prepared in the same manner as for the investigation of the isothermal section of this system.

The crystal structures of  $\sim$ Sc<sub>5</sub>Ce<sub>0.5</sub>Ge<sub>4.5</sub> (1) and  $\sim$ Sc<sub>2</sub>Ce<sub>5</sub>Ge<sub>6</sub> (4) are not determined.

Fig. 118. Sc–Ce–Ge, isothermal section at 870 K.

### 5.1.4. Sc–Pr–Ge

At present, the phase relations are unknown for the system Sc–Pr–Ge. The formation of two ternary germanides was observed in the course of searching for isostructural series of compounds.

$\text{Sc}_3\text{Pr}_{1.22}\text{Ge}_4$  was found to be isotypic with  $\text{Sc}_3\text{Ce}_2\text{Si}_4$ ,  $a=0.7116$ ,  $b=1.4059$ ,  $c=0.7576$  (X-ray powder diffraction; Shpyrka et al. 1990).  $\text{ScPrGe}$  belongs to the  $\text{ScCeSi}$  type,  $a=0.4325$ ,  $c=1.5874$  (X-ray powder diffraction; Shpyrka 1990). For the experimental details, see  $\text{Sc-Y-Ge}$ .

### 5.1.5. $\text{Sc-Nd-Ge}$

The isothermal section for the  $\text{Sc-Nd-Ge}$  system at 870 K (fig. 119) was constructed by Shpyrka (1990) employing X-ray phase and microstructural analyses of 112 alloys which were arc melted and annealed for 400 h in sealed quartz ampoules. The phase relations within the  $\text{Sc-Nd-Ge}$  system at 870 K are characterized by the existence of three ternary compounds and by the formation of substitutional solid solutions originating at  $\text{Nd}_5\text{Ge}_3$

Fig. 119.  $\text{Sc-Nd-Ge}$ , isothermal section at 870 K.

(dissolves 12.5 at.% Sc),  $\text{Nd}_5\text{Ge}_4$  (10 at.% Sc),  $\text{NdGe}$  (5 at.% Sc),  $\text{NdGe}_{2-x}$  (8 at.% Sc),  $\text{Sc}_{11}\text{Ge}_{10}$  (8 at.% Nd), and  $\text{Sc}_5\text{Ge}_3$  (5 at.% Nd). The purity of the starting metals was Sc 99.92 mass%, Nd 99.44 mass%, and Ge 99.99 mass%. The solubilities of third component in other binary compounds were reported to be <5 at.%.

The crystal structures of  $\text{Sc}_3\text{Nd}_{1.22}\text{Ge}_4$  (1) ( $\text{Sc}_3\text{Ce}_2\text{Ge}_4$  type;  $a=0.7119$ ,  $b=1.4065$ ,  $c=0.7574$ ) and  $\text{ScNdGe}$  (2) ( $\text{ScCeSi}$  type;  $a=0.43106$ ,  $c=1.5823$ ) were investigated by Shpyrka et al. (1990) and Shpyrka (1990), respectively, employing X-ray powder diffraction. For experimental details, see  $\text{Sc-Nd-Ge}$ , isothermal section.

The crystal structure of  $\sim\text{Sc}_2\text{Nd}_5\text{Ge}_6$  (3) was not investigated.

### 5.1.6. $\text{Sc-Sm-Ge}$

No phase diagram is available for the  $\text{Sc-Sm-Ge}$  system; however two ternary compounds were observed and characterized.

$\text{Sc}_3\text{Sm}_{1.22}\text{Ge}_4$  was found to be isotypic with  $\text{Sc}_3\text{Ce}_2\text{Si}_4$ ,  $a=0.7102$ ,  $b=1.4020$ ,  $c=0.7546$  (X-ray powder diffraction; Shpyrka et al. 1990).  $\text{ScSmGe}$  belongs to the  $\text{ScCeSi}$  type,  $a=0.4264$ ,  $c=1.5623$  (X-ray powder diffraction; Shpyrka 1990). For the experimental details, see  $\text{Sc–Y–Ge}$ .

The phase relations along the section  $\text{ScGe}_2\text{–SmGe}_2$  were investigated by Shpyrka (1990); the formation of a ternary compound  $\text{Sc}_{0.12}\text{Sm}_{0.22}\text{Ge}_{0.66}$  with an unknown structure type was observed.

#### 5.1.7. *Sc–Eu–Ge*

Little information exists about the  $\text{Sc–Eu–Ge}$  system; only one ternary germanide was characterized.  $\text{ScEuGe}$  was found to be isotypic with a  $\text{ScCeSi}$  type,  $a=0.4270$ ,  $c=1.5636$  (X-ray powder diffraction; Shpyrka 1990). For the experimental details, see  $\text{Sc–Y–Ge}$ .

#### 5.1.8. *Sc–Gd–Ge*

No complete phase diagram is available for the  $\text{Sc–Gd–Ge}$  system; phase relations along  $\text{ScGe}_2\text{–GdGe}_2$  were studied by Shpyrka (1990). From X-ray powder diffraction data for arc melted alloys annealed at 870 K, the solubility of  $\text{ScGe}_2$  in  $\text{GdGe}_2$  was found to extend up to 8 at.% Sc.

#### 5.1.9. *Sc–Tb–Ge*

The only phase diagram information on the system  $\text{Sc–Tb–Ge}$  is due to Shpyrka (1990) who investigated ternary arc melted alloys annealed at 870 K in the  $\text{ScGe}_2\text{–TbGe}_2$  quasibinary system by means of X-ray powder diffraction. The solubility of  $\text{ScGe}_2$  in  $\text{TbGe}_2$  extends to 6 at.% Sc.

#### 5.1.10. *Sc–Dy–Ge*

The phase equilibria in the  $\text{Sc–Dy–Ge}$  system (fig. 120) were investigated by Shpyrka and Mokra (1991) using X-ray phase and microstructural analyses of alloys which were arc melted and subsequently annealed in evacuated silica tubes for 350 h at 870 K and finally quenched in water. The starting materials were Sc 99.92 mass%, Dy 99.90 mass% and Ge 99.99 mass%. The phase relations are characterized by the existence of three ternary compounds and the formation of continuous solid solution  $(\text{Sc,Dy})_5\text{Ge}_3$  originating at the isotypic binary compounds. The binary compounds  $\text{DyGe}_{1.33}$ ,  $\text{ScGe}_2$ ,  $\text{Sc}_{11}\text{Ge}_{10}$  and  $\text{Dy}_{11}\text{Ge}_{10}$  dissolve 20, 18, 8 and 8 at.% of the third component, respectively.

The three compounds observed by Shpyrka and Mokra (1991) were  $\text{Sc}_{1.8}\text{Dy}_{3.2}\text{Ge}_4$  (1) ( $\text{Sm}_5\text{Ge}_4$  type,  $a=0.7346$ ,  $b=1.4295$ ,  $c=0.7555$ );  $\text{Sc}_{2.7}\text{Dy}_{2.3}\text{Ge}_4$  (3) (isotypic with  $\text{Sm}_5\text{Ge}_4$ ,  $a=0.7260$ ,  $b=1.4151$ ,  $c=0.7477$ ); and  $\sim\text{ScDy}_2\text{Ge}_6$  (2) which crystallizes with an unknown structure type.

Fig. 120. Sc–Dy–Ge, isothermal section at 870 K.

5.2. Y–R'–Ge systems

5.2.1. Y–Ce–Ge

The isothermal section of the Y–Ce–Ge phase diagram at 870 K (fig. 121) was constructed by Shpyrka (1990) using X-ray powder diffraction data of 163 arc melted alloys annealed for 400 h. The purity of the starting components was Y 99.90 mass%, Ce 99.56 mass%, and Ge 99.99 mass%. The phase relations are characterized by the existence of two ternary compounds and by the formation of two continuous solid solutions between binary

Fig. 121. Y–Ce–Ge, isothermal section at 870 K.

$RGe_{2-x}$  and  $R_5Ge_3$  compounds. Three solid solution ranges were found to exist within the Y–Ce–Ge system at 870 K: Ce in  $Y_2Ge_3$  (up to 20 at.%), Ce in  $Y_{11}Ge_{10}$  (up to 18 at.%) and Y in  $Ce_5Ge_4$  (up to 20 at.%).

$Y_{0.2}Ce_{0.8}Ge$  (1) was said to crystallize with CrB type structure,  $a=0.447$ ,  $b=1.1095$ ,  $c=0.4064$  (Shpyrka 1990; X-ray powder diffraction).

$Y_{3.2}Ce_{1.8}Ge_4$  (2) belongs to the  $Sm_5Ge_4$  type structure,  $a=0.760$ ,  $b=1.463$ ,  $c=0.756$  (Shpyrka 1990; X-ray powder diffraction).

### 5.3. La–R<sup>l</sup>–Ge systems

#### 5.3.1. La–Ce–Ge

The phase equilibria in the La–Ce–Ge system at 870 K (fig. 122) were investigated by Shpyrka (1988) by means of X-ray phase analysis and partly microstructural analysis of alloys which were arc melted and subsequently annealed in evacuated silica tubes for 350 h and finally quenched in water. The starting materials were La 99.79 mass%, Ce 99.56 mass%, and Ge 99.99 mass%. The phase relations are characterized by the formation of continuous solid solutions originating at the isotypic binary compounds.

Fig. 122. La–Ce–Ge, isothermal section at 870 K.

#### 5.3.2. La–Gd–Ge

The phase relations in the La–Gd–Ge ternary system at 873 K within 40–100 at.% Ge were investigated by Stetskiy et al. (1995) using X-ray powder and partly microstructural analyses. Samples were obtained by arc melting, and homogenized at 873 K for 500 h. The formation of the continuous solid solution  $(La, Gd)Ge_{2-x}$  ( $\alpha$ -ThSi<sub>2</sub> structure type) was found and solubility of Gd (~10 at.%) in  $LaGe_{2-x}$  ( $\alpha$ -GdSi<sub>2</sub> structure type) was determined.

#### 5.4. Ce-R'-Ge systems

##### 5.4.1. Ce-Gd-Ge

The phase equilibria in the Ce-Gd-Ge system (fig. 123) were investigated by Shpyrka et al. (1986) by means of X-ray phase analysis of 170 alloys which were arc melted and subsequently annealed in evacuated silica tubes for 350 h at 870 K and finally quenched in water. The starting materials were Ce 99.56 mass%, Gd 99.85 mass%, and Ge 99.99 mass%. The phase relations are characterized by the formation of three continuous solid solutions between isotypic binary compounds:  $(\text{Ce}, \text{Gd})\text{Ge}_{2-x}$ ,  $(\text{Ce}, \text{Gd})_5\text{Ge}_4$  and  $(\text{Ce}, \text{Gd})_5\text{Ge}_3$ . The binary compounds GdGe,  $\text{Ce}_3\text{Ge}$  and  $\text{Gd}_{1.04}\text{Ge}_{1.56}$  dissolve 40, 20 and 16 at.% of the third component, respectively.

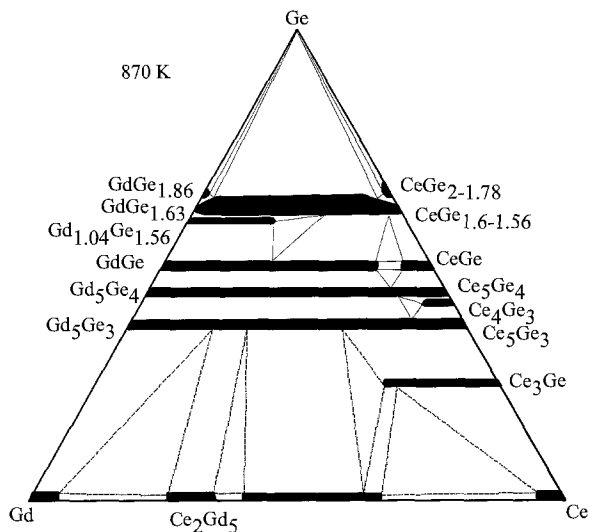

Fig. 123. Ce-Gd-Ge, isothermal section at 870 K.

##### 5.4.2. Ce-Dy-Ge

Little information exists about the Ce-Dy-Ge system; only one ternary germanide was characterized.  $\text{Ce}_{0.8}\text{Dy}_{0.2}\text{Ge}$  was found to be isotypic with CrB,  $a=0.4465$ ,  $b=1.1064$ ,  $c=0.4050$  (X-ray powder diffraction; Shpyrka 1990). For the experimental details, see Y-Ce-Ge.

##### 5.4.3. Ce-Ho-Ge

No phase diagram is available for the Ce-Ho-Ge system; however one ternary compound was observed and characterized in the course of searching for isostructural series of compounds.  $\text{Ce}_{0.8}\text{Ho}_{0.2}\text{Ge}$  was reported to be isotypic with CrB,  $a=0.4475$ ,  $b=1.1092$ ,  $c=0.4063$  (X-ray powder diffraction; Shpyrka et al. 1990). For the experimental details, see Y-Ce-Ge.

#### 5.4.4. Ce–Er–Ge

At present, phase relations are unknown for the system Ce–Er–Ge; the formation of one ternary germanide was observed. Shpyrka (1990) reported the crystallographic characteristics for  $\text{Ce}_{0.8}\text{Er}_{0.2}\text{Ge}$ : CrB-type structure,  $a=0.4470$ ,  $b=1.1104$ ,  $c=0.4072$  (X-ray powder diffraction). For experimental details, see Y–Ce–Ge.

#### 5.4.5. Ce–Tm–Ge

No phase diagram is available for the Ce–Tm–Ge system; however one ternary compound was observed and characterized by Shpyrka (1990):  $\text{Ce}_{0.8}\text{Tm}_{0.2}\text{Ge}$ , CrB-type structure,  $a=0.4485$ ,  $b=1.1110$ ,  $c=0.4073$  (X-ray powder diffraction). For experimental details, see Y–Ce–Ge.

#### 5.4.6. Ce–Lu–Ge

The phase equilibria in the Ce–Lu–Ge system at 870 K (fig. 124) were investigated by Shpyrka (1990) by means of X-ray phase and microstructural analyses of 143 alloys which were arc melted and subsequently annealed in evacuated silica tubes for 350 h and finally quenched in water. The starting materials were Ce 99.56 mass%, Lu 99.98 mass%, and Ge 99.99 mass%. The phase relations are characterized by the existence of two ternary compounds and the formation of continuous solid solution  $(\text{Ce},\text{Lu})_5\text{Ge}_3$  between the isotypic binary compounds. The binary compounds  $\text{Ce}_3\text{Ge}$ ,  $\text{Lu}_{0.9}\text{Ge}_2$  and  $\text{LuGe}_{1.5}$  dissolve 12.5, 10 and 10 at.% of third component, respectively.

The two ternary compounds observed by Shpyrka (1990) were  $\text{Ce}_{0.45-1.35}\text{Lu}_{4.55-3.65}\text{Ge}_4$  (1) ( $a=0.7389-0.7469$ ,  $b=1.4305-1.4436$ ,  $c=0.7607-0.7649$ ) and  $\text{Ce}_{3.25}\text{Lu}_{1.75}\text{Ge}_4$  (2) ( $a=0.7666$ ,  $b=1.4925$ ,  $c=0.7649$ ). Both phases are isotypic with  $\text{Sm}_5\text{Ge}_4$ .

Fig. 124. Ce–Lu–Ge, isothermal section at 870 K.

### 5.5. *Sm-R'-Ge systems*

#### 5.5.1. *Sm-Lu-Ge*

Shpyrka investigated the phase formation within the  $\text{SmGe}_2\text{-LuGe}_2$  section at 870 K; three ternary phases were observed:  $\sim\text{Sm}_{26}\text{Lu}_8\text{Ge}_{66}$  (unknown type),  $\sim\text{Sm}_{24}\text{Lu}_{10}\text{Ge}_{66}$  ( $\text{DyGe}_{1.85}$  type) and  $\sim\text{Sm}_{22}\text{Lu}_{12}\text{Ge}_{66}$  ( $\text{HoGe}_2$  type). For sample preparation, see Ce-Lu-Ge.

### 5.6. *Dy-R'-Ge systems*

#### 5.6.1. *Dy-Ho-Ge*

The only information on the phase relations in the Dy-Ho-Ge system is due to Shpyrka (1990) who investigated the  $\text{DyGe}_2\text{-HoGe}_2$  section by means of X-ray powder diffraction. The samples were prepared by arc melting followed by annealing at 870 K for 400 h. The purity of the starting materials was Dy 99.83 at.%, Ho 99.50 at.%, and Ge 99.99 at.%. The solubility of  $\text{HoGe}_2$  in  $\text{DyGe}_2$  extends to 15 at.% Ho. One ternary compound  $\text{Dy}_{0.19-0.17}\text{Ho}_{0.19-0.21}\text{Ge}_{0.66}$  with unknown structure was observed. The solubility of  $\text{DyGe}_2$  in  $\text{HoGe}_2$  extends to 8.5 at.% Ho.

### 5.7. *Er-R'-Ge systems*

#### 5.7.1. *Er-Tm-Ge*

No ternary phase diagram exists for the Er-Tm-Ge system; however the formation of a ternary compound  $\sim\text{Er}_{0.24}\text{Tm}_{0.12}\text{Ge}_{0.66}$  with an unknown structure was reported from an X-ray investigation of the  $\text{ErGe}_2\text{-TmGe}_2$  section. The solubility of  $\text{TmGe}_2$  in  $\text{ErGe}_2$  extends to 3 at.% Tm, whereas the solubility of  $\text{ErGe}_2$  in  $\text{TmGe}_2$  extends to 20 at.% Er.

## 6. Discussion

### 6.1. *Peculiarities of the interactions in the R-s element-Ge systems*

#### 6.1.1. *R-Li-Ge systems*

From 16 rare-earth ternary systems with lithium and germanium the isothermal sections for 10 systems have been established over the whole concentration region.

The main peculiarity of all ternary systems with rare-earth metals concerns the influence which the component interaction in the terminal binary systems has on the ternary systems. The binary immiscibility region R-Li always extends into the ternaries up to a maximum content of 17–26 at.% Ge. As a consequence, a small number of ternary compounds is formed, with a maximum observed for the Ho-Li-Ge system (7 intermetallics). All ternary compounds, as a rule, have a narrow homogeneity range, which is connected with the pronounced difference in characteristic alloying parameters of the interacting components.

Table 31  
Isotypic compounds of the ternary R–Li–Ge systems<sup>a</sup>

Structure type	La	Ce	Pr	Nd	Sm	Eu	Gd	Tb	Dy	Ho	Er	Tm	Yb	Lu	Y
Ce <sub>2</sub> Li <sub>2</sub> Ge <sub>3</sub>	+	+	+	+	+		–			–	–	–	–	–

<sup>a</sup>An empty cell means that the alloy of this composition was not investigated; a plus sign means that the compound exists, a minus sign that it was not observed.

Analysis of the compositions and crystal structures of the experimentally observed ternary intermetallics established a sharp differentiation between systems belonging to the ceric or to the yttric subgroup. This situation is illustrated by table 31.

From the investigated series of isostructural compounds, intermetallics of equiatomic composition with ZrNiAl structure are typical for both the ceric and the yttric subgroups. Other series exist either in the ceric subgroup (RLi<sub>2</sub>Ge, R<sub>2</sub>LiGe<sub>6</sub>, R<sub>2</sub>LiGe<sub>5</sub>, R<sub>2</sub>Li<sub>2</sub>Ge<sub>3</sub>) or in the yttric subgroup (R<sub>4</sub>LiGe<sub>4</sub>, R<sub>3</sub>Li<sub>2</sub>Ge<sub>3</sub>, RLi<sub>1-x</sub>Ge<sub>2</sub>). The system Gd–Li–Ge occupies the intermediate position with compounds crystallizing in structural types typical for the ceric subgroup (CaLiSi<sub>2</sub>), as well as types typical for the yttric subgroup (Tm<sub>4</sub>LiGe<sub>4</sub>) or for both subgroups (ZrNiAl). However the systems of a particular subgroup are not complete analogues. For example, in the Ce–Li–Ge system, a compound of composition Ce<sub>26</sub>Li<sub>5</sub>Ge<sub>22</sub> exists which has not been found in the corresponding systems of this subgroup. Also the intermetallic of equiatomic composition with the ZrNiAl structure does not form with cerium. In the systems with Nd and Sm the homologous compounds with Pr<sub>2</sub>LiGe<sub>6</sub> structure, which are formed with cerium and praseodymium, have not been found. Also, in the Sm–Li–Ge system there is no compound with AlCr<sub>2</sub>C structure.

For the yttric subgroup the biggest differences are observed for the Yb–Li–Ge system. The formation of two compounds (Yb<sub>8</sub>LiGe<sub>13</sub> and Yb<sub>5</sub>Li<sub>4</sub>Ge<sub>4</sub>) with new structure types which do not occur within any other system of this subgroup has been found for the ytterbium–lithium–germanium combinations. This is probably due to the tendency of ytterbium to be divalent or mixed-valent.

Compounds of equiatomic composition with rare-earth metals of the yttric and cerium subgroups crystallize with the ZrNiAl type whereas scandium germanide of equiatomic composition forms the MgAgAs type.

Due to a noticeable lack of information on ternary R–Li–Ge systems, it is still difficult to establish a relation between the number of compounds formed per individual system

and the chemical nature of the interacting elements. From the data available, one can distinguish some established regularities:

- (i) the number of compounds formed per system increases with increasing differences in atom size, electronegativity, electronic structure and thermodynamic properties;
- (ii) a separation of systems into ceric and yttric subgroups is observed; the Gd–Li–Ge system occupies an intermediate position between these subgroups;
- (iii) binary immiscibility always extends into the corresponding ternary system.

### 6.1.2. R–Mg–Ge

Interaction of rare earths with magnesium and germanium has not been studied sufficiently; few ternary compounds were observed and investigated (EuMgGe, YbMgGe and EuMg<sub>3</sub>Ge<sub>3</sub>). Therefore it is impossible to draw any conclusions with respect to the alloying behavior of these metals.

## 6.2. Peculiarities of the interactions in the R–p element–Ge systems

### 6.2.1. R–B–Ge systems

The characteristic features of the interaction of boron and germanium with the rare earths is the absence of ternary compounds and the lack of solid solubility of the third component in the binary phases.

### 6.2.2. R–Al–Ge systems

In spite of the fact that the partial isothermal sections (0–33 at.% R) have been investigated only for four ternary systems, it is possible to draw some conclusions on the interaction of components in these systems (see table 32). Similarly to the ternary R–Li–Ge combinations, a differentiation exists between ternary systems containing light and heavy lanthanides; the Gd–Al–Ge system occupies an intermediate position between ceric and yttric subgroups:

Table 32  
Isotypic compounds of the ternary R–Al–Ge systems

Structure type	La	Ce	Pr	Nd	Sm	Eu	Gd	Tb	Dy	Ho	Er	Tm	Yb	Lu	Y	Sc
CaAl <sub>2</sub> Si <sub>2</sub>	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	–
Ba <sub>2</sub> Cd <sub>3</sub> Bi <sub>4</sub>	+	+	+	+	+	–	+	+	+	+	+	–	–	–	–	–
La <sub>2</sub> AlGe <sub>6</sub>	+	+	+	+	+	–	+	–	–	–	–	–	–	–	–	–
α-ThSi <sub>2</sub>	+	+	+	+	+	+	+	–	–	–	–	–	–	–	–	–
YAlGe	–	–	–	–	–	–	+	+	+	+	+	+	+	+	+	+
AlB <sub>2</sub>	+	+		+			–									–

<sup>a</sup>An empty cell means that the alloy of this composition was not investigated; a plus sign means that the compound exists, a minus sign that it was not observed.

- (i) the  $R_2AlGe_6$  and  $\alpha-ThSi_2$  structures are typical for the ceric subgroup, and the Gd-containing compounds are the ending members of these isotypic series;
- (ii) the  $YAlGe$  structure is typical for the yttric subgroup, and the Gd-containing compound is the first member of this isostructural series;
- (iii) the  $CaAl_2Si_2$  type occurs in all systems except of for scandium;
- (iv) the  $GdAlGe$  compound has two polymorphic modifications,  $\alpha-ThSi_2$  and  $YAlGe$ .

### 6.2.3. *R–Ga(In, C)–Ge systems*

Little information exists on the interaction of gallium (indium, carbon) with germanium and the rare earths. From the available data, one notices that for the gallium-containing compounds the most typical structures are the  $AlB_2$ -,  $ThSi_2$ - and  $Ce_2GaGe_6$ -types. Only one series of isotypic compounds was observed both for the rare-earth–indium–germanium combinations ( $Mo_2NiB_2$ ) and for the carbon-containing ternary alloys ( $R_5CGe_3$ ).

### 6.2.4. *R–Si–Ge systems*

The R–Si–Ge systems are characterized by the presence of two components with similar crystallochemical behavior. This is the main reason why limited or continuous solid solutions are formed between the isotypic binary compounds. These solid solutions often show various deviations from linearity in the unit cell volume versus concentration plots.

Two ternary compounds were found only in the Y–Si–Ge system. They have the crystal structures of binary  $YSi_2$  and  $YGe_2$  compounds.

## 6.3. *Peculiarities of the interactions in the R–d element–Ge systems*

The majority of experimental investigations deals with Fe, Co, Ni and Cu. Therefore, our discussion will be based on the interaction peculiarities of rare earths and germanium with the above-mentioned elements and their electronic analogues.

### 6.3.1. *R–Fe–Ge systems*

From the results reviewed in this chapter, some common regularities of the interaction of rare-earth metals with iron and germanium can be drawn. The number of ternary compounds formed with light rare-earth elements, iron and germanium monotonously increases from lanthanum to samarium. No ternary compounds were found with europium, which is probably due to its divalent nature, compared to trivalency for the other rare earths. Among the heavy lanthanides, Tm forms the largest number of ternary compounds with iron and germanium.

The ternary systems R–Fe–Ge are characterized by various stoichiometries and crystal structures of the existing ternary compounds, depending on the rare-earth metal (table 33). As one can see, the most prevailing structure types are  $CeGa_2Al_2$  and  $CeNiSi_2$ . Compounds with  $AlB_2$ -,  $BaNiSn_3$ -,  $Nd_6Fe_{13}Si$ - and  $Sm_4Co_{1-x}Ge_7$ -type structures were observed in ternary systems containing light lanthanides; compounds with  $CeGa_2Al_2$ -

Table 33  
Isotypic compounds in the ternary R–Fe–Ge systems<sup>a</sup>

Structure type	La	Ce	Pr	Nd	Sm	Eu	Gd	Tb	Dy	Ho	Er	Tm	Yb	Lu	Y	Sc

YCo <sub>6</sub> Ge <sub>6</sub>	-	-	+	+	+	-	+	+	+	+	+	+	+	+	+	-
Tb <sub>117</sub> Fe <sub>52</sub> Ge <sub>112</sub>	-	+	-	+	-	-	-	+	+	+	+	+	-	+	+	-
ZrFe <sub>4</sub> Si <sub>2</sub>	-	-	-	-	-	-	-	+	+	+	+	+	+	+	+	-
Gd <sub>6</sub> Cu <sub>8</sub> Ge <sub>8</sub>	-	-	-	-	-	-	-	-	+	+	+	+	-	+	-	-
Hf <sub>3</sub> Ni <sub>2</sub> Si <sub>3</sub>	-	-	-	-	-	-	-	-	-	-	+	-	-	+	-	-
Tm <sub>9</sub> Fe <sub>10</sub> Ge <sub>10</sub>	-	-	-	-	-	-	-	-	-	-	+	+	+	-	-	-
BaNiSn <sub>3</sub>	+	+	-	-	-	-	-	-	-	-	-	-	-	-	-	-
AlB <sub>2</sub>	+	-	-	+	+	-	-	-	-	-	-	-	-	-	-	-
Nd <sub>6</sub> Fe <sub>13</sub> Si	-	+	+	-	-	-	-	-	-	-	-	-	-	-	-	-
Sm <sub>4</sub> Co <sub>1-x</sub> Ge <sub>7</sub>	-	+	+	+	+	-	-	-	-	-	-	-	-	-	-	-

<sup>a</sup>An empty cell means that the alloy of this composition was not investigated; a plus sign means that the compound exists, a minus sign that it was not observed.

CeNiSi<sub>2</sub>-, YCo<sub>6</sub>Ge<sub>6</sub>- and Tb<sub>117</sub>Fe<sub>52</sub>Ge<sub>112</sub>-type structures are found for both the light and heavy rare-earth elements; and ZrFe<sub>4</sub>Si<sub>2</sub>-, Gd<sub>6</sub>Cu<sub>8</sub>Ge<sub>8</sub>-, Tm<sub>9</sub>Fe<sub>10</sub>Ge<sub>10</sub>- and Hf<sub>3</sub>Ni<sub>2</sub>Si<sub>3</sub>-type structures are typical only for the heavy lanthanides.

The range of formation of ternary R–Fe–Ge compounds is restricted to concentrations of less than ~42 at.% rare-earth metal; R<sub>117</sub>Fe<sub>52</sub>Ge<sub>112</sub> (Tb<sub>117</sub>Fe<sub>52</sub>Ge<sub>112</sub> type) is the terminal R-rich phase. Ternary compounds with light lanthanides are found predominantly in the range 40–70 at.% Ge, whereas the heavy rare-earth elements form compounds primarily in the concentration region from 28 to 50 at.% Ge.

### 6.3.2. R–Co–Ge systems

Interactions of R with cobalt and germanium have been sufficiently studied to draw some conclusions, i.e. the phase diagrams for 12 ternary R–Co–Ge systems have been established. Most of them are characterized by a large number of ternary compounds. Substitution of an R element essentially affects the alloying behaviour of elements that is displayed in the number of compounds formed. The maximum number of ternary phases (20) has been observed for the samarium-containing system. The Eu–Co–Ge system strongly differs from all other R–Co–Ge systems by the number of ternary compounds. The isotypic series of compounds which are observed in these systems are listed in table 34.

Dimorphism phenomena are characteristic for the R<sub>2</sub>Co<sub>3</sub>Ge<sub>5</sub> compounds (Lu<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub>-type ↔ U<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub>-type) (R = Ce–Sm, Gd). Morphotropic transformation was noticed for

Table 34

the RCoGe compounds: from structure type PbFCl (CeCoGe, PrCoGe, NdCoGe) to structure type TiNiSi (SmCoGe, GdCoGe). No compound of equiatomic composition was observed within the Eu-Co-Ge system.

The maximum number of ternary compounds in the R-3d element-Ge systems with Pr, Nd, Sm, Tb, Ho, Er, Tm is formed with cobalt.

### 6.3.3. R-Ni-Ge systems

The primary intention of this section is to discuss and compare the interaction of the components in the R-Ni-Ge systems. According to sect. 4, the phase equilibria have been investigated for 12 ternary systems.

Concerning the number and the composition of compounds formed, the interaction of the components in the ternary systems R-Ni-Ge is rather complicated and varies considerably.

In this respect the most significant differences are observed in the light rare-earth group, between Ce and Eu. The ternary nickel germanides with cerium (20 compounds) exist within a wide concentration region from 7.5 to 62.5 at.% Ce, whereas the ternary phases in the Eu-Ni-Ge system (six compounds) occur between 7.5 and 33.3 at.% Eu.

Table 35  
Isotypic compounds of the ternary R–Ni–Ge systems<sup>a</sup>

Structure type	La	Ce	Pr	Nd	Sm	Eu	Gd	Y	Tb	Dy	Ho	Er	Tm	Yb	Lu	Sc

<sup>a</sup>An empty cell means that the alloy of this composition was not investigated; a plus sign means that the compound exists, a minus sign that it was not observed.

The maximum rare-earth concentration in the ternary nickel germanides of Pr (Nd, Sm) is approximately 50 at. %.

The formation of ternary phases with the rare-earth elements from Tb through Tm (including Y) exhibits a close resemblance between systems. Moreover, the Y(Tb, Dy)–Ni–Ge systems are identical. This is also true for the Ho(Er, Tm)–Ni–Ge systems.

It should be noted, that the concentration region spanned by the compounds formed for the R elements from Tb through Tm (including Y) is somewhat narrower in comparison with R–Ni–Ge systems, where R = Ce, Pr, Nd, Sm, Eu (from 11 to 50 at. % R). The maximum Ge concentration in the ternary nickel germanides of the light rare-earth elements as well as of the heavy rare earths is 66.6 at. % (in the R<sub>2</sub>NiGe<sub>6</sub> compounds).

Another interesting feature of the R–Ni–Ge systems is the solubility of Ge in the Ni-rich binary compounds R<sub>2</sub>Ni<sub>17</sub> and RNi<sub>5</sub>.

Table 35 gives a survey of the isotypic series of the compounds in the R–Ni–Ge systems. The compounds of the CeGa<sub>2</sub>Al<sub>2</sub>-, CeNiSi<sub>2</sub>-, AlB<sub>2</sub>-, Ce<sub>2</sub>CuGe<sub>6</sub>-, La<sub>3</sub>NiGe<sub>2</sub>-, TiNiSi- and SmNiGe<sub>3</sub>-type structures are found for both the light and the heavy rare-earth elements. The compounds of the CeNi<sub>8.5</sub>Si<sub>4.5</sub>-, U<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub>-, U<sub>3</sub>Ni<sub>4</sub>Si<sub>4</sub>- and La<sub>11</sub>Ni<sub>4</sub>Ge<sub>6</sub>-type structures are observed in ternary systems containing light lanthanides. The Sc<sub>3</sub>Ni<sub>11</sub>Si<sub>4</sub>-, NdIrGe<sub>2</sub>- and LuNiGe-type structures occur typically only for the

heavy lanthanides. The  $\text{RNi}_5\text{Ge}_3$  compounds of  $\text{YNi}_5\text{Si}_3$  structure type, unexpectedly, occur solely with samarium and with the heavy rare-earth elements. In addition to the compounds listed in table 35, the crystal structure has been solved for the following germanides:  $\text{La}_2\text{NiGe}$  (space group  $I4/mcm$ ),  $\text{La}_8\text{NiGe}_5$  (space group  $Pmmn$ ),  $\text{La}(\text{Ni}, \text{Ge})_{13}$  (space group  $Fm3c$ ),  $\text{Ce}_5\text{NiGe}_2$  (space group  $P4/ncc$ ),  $\text{SmNi}_3\text{Ge}_3$  (space group  $I4/mmm$ ),  $\text{EuNiGe}$  (space group  $P2_1/b$ ),  $\text{EuNiGe}_3$  (space group  $I4mm$ ) and  $\text{Er}_3\text{Ni}_2\text{Ge}_3$  (space group  $Cmcm$ ). All these compounds are the unique representatives of the indicated structure types in the R–Ni–Ge systems.

As one can see from table 35, a few morphotropic transformations have been observed in the systems under discussion. A brief description follows:

- (i) The  $\text{RNiGe}_2$  compounds. The compounds with 1:1:2 composition when R is a light rare-earth element crystallize in the  $\text{CeNiSi}_2$ -type structure. The compounds of the same structure type for the heavy rare-earth elements have been found to form with a nonstoichiometric composition and are defective of Ni atoms. Furthermore, the compounds of stoichiometric composition with Ho, Er, Tm and Lu have been found to crystallize with the  $\text{NdIrGe}_2$ -type structure.
- (ii) The  $\text{R}(\text{Ni}, \text{Ge})_{13}$  compounds. The following morphotropic transformation has been observed for the light rare-earth elements: from  $\text{La}(\text{Ni}, \text{Ge})_{13}$  ( $\text{NaZn}_{13}$  type, space group  $Fm3c$ ) to  $\text{R}(\text{Ni}, \text{Ge})_{13}$  ( $\text{R} = \text{Ce–Nd}, \text{Eu}, \text{CeNi}_{8.5}\text{Si}_{4.5}$  type, space group  $I4/mcm$ ).
- (iii) The  $\text{RNiGe}_3$  compounds. In this series the  $\text{SmNiGe}_3$  structure type (space group  $Cmmm$ ) was observed for the compounds of the lanthanides except Eu and Yb. The  $\text{EuNiGe}_3$  compound crystallizes in the  $\text{BaNiSn}_3$  type (space group  $I4mm$ ).
- (iv) The  $\text{RNiGe}$  compounds. A similar transformation, which also is caused, probably, by the peculiar behavior of the Eu atom has been observed in the  $\text{RNiGe}$  series of compounds:  $\text{Ce}(\text{Pr–Sm})\text{NiGe}$  ( $\text{TiNiSi}$ -type) to  $\text{EuNiGe}$  (own structure type)  $\rightarrow$   $\text{Gd}(\text{Tb–Lu})\text{NiGe}$  ( $\text{TiNiSi}$ -type).

The  $\text{TmNiGe}$  and  $\text{LuNiGe}$  compounds exhibit dimorphism. The  $\text{TiNiSi}$  type  $\leftrightarrow$   $\text{LuNiGe}$  type transition temperature is 1630 K for  $\text{TmNiGe}$  and 1570 K for  $\text{LuNiGe}$ .

The compound  $\text{Ce}_5\text{NiGe}_2$  also occurs in two modifications: the compound in its own structure type (high-temperature modification) transforms into a compound of unknown structure type (low-temperature modification).

Thus, the comparison of the R–Ni–Ge systems, carried out above, shows a similarity in the interaction of rare-earth metals with nickel and germanium with the exception of europium, which forms a considerably smaller number of compounds. This is consistent with europium's divalent character, and its similar behavior observed in the other Eu–3d element–Ge systems. At the same time, the type of interaction and the crystal structures of compounds formed are different for the elements of the light and heavy lanthanides. The only two ternary germanides of scandium, which are isotypic with lanthanide-containing compounds, are  $\text{ScNiGe}$  (structure type  $\text{TiNiSi}$ ) and  $\text{Sc}_3\text{Ni}_{11}\text{Ge}_4$  (structure type  $\text{Sc}_3\text{Ni}_{11}\text{Ge}_4$ ).

6.3.4. *R-Cu(Ag, Au)-Ge systems*

In contradiction to earlier reviewed R-Fe(Co, Ni)-Ge systems with a brightly pronounced distinction between systems containing light rare earths and systems containing heavy rare earths, the alloying behavior in R-Cu(Ag, Au)-Ge systems is of an analogous type.

The predominant majority of ternary compounds exists within the narrow concentration region from 20 to 33 at.% R.

Table 36 lists the isotypic series of the compounds in the R-Cu(Ag, Au)-Ge systems. Ternary phases of Ce<sub>2</sub>Cu<sub>3</sub>Ge<sub>3</sub>- and CeNiSi<sub>2</sub>-type structures are found only in the R-Cu-Ge system and are not included in table 36.

Table 36

	Ag	-	-	+	+	+	-	+			-				-		-
	Au					-											-

<sup>a</sup>An empty cell means that the alloy of this composition was not investigated; a plus sign means that the compound exists, a minus sign that it was not observed.

The compounds of equiatomic composition are found to crystallize mainly in hexagonal basis. The following morphotropic transformation was observed in the RCuGe compounds: (La-Sm, Gd)CuGe (AlB<sub>2</sub> structure type) → (Y, Tb-Lu)CuGe (CaIn<sub>2</sub> structure type) → ScCuGe (ZrNiAl structure type). For the ternary RAgGe compounds the following structure types are characteristic: (La, Ce, Pr)AgGe (LiGaGe structure type) → EuAgGe (AlB<sub>2</sub> structure type) → (Gd-Lu, Sc)AgGe (ZrNiAl structure type). The RAuGe compounds crystallize with the LiGaGe structure type.

Unlike other lanthanides, europium forms equiatomic compounds with an orthorhombic structure: EuCuGe (structure types TiNiSi and CaCuGe), EuAgGe (structure type KHg<sub>2</sub>) and EuAuGe (own structure type).

### 6.3.5. R–platinum metals–Ge systems

Although the isothermal sections are completely or partly constructed only for 18 ternary systems from 96 possible R–platinum metals–Ge combinations, one can see that with respect to the formation of compounds in the ternary R–M–Ge systems, Ru and Os show behavior similar to Rh and Ir (see table 37). Analysis of the compositions and crystal structures of the experimentally observed ternary germanides of platinum metals established a likeness between platinum- and palladium-containing systems (see table 38). Since information on the systematic investigations of the R–Pt–Ge systems is still lacking, only some regularities on the interaction of these components are observed.

Table 37

<sup>a</sup>An empty cell means that the alloy of this composition was not investigated; a plus sign means that the compound exists, a minus sign that it was not observed.

As one can see from table 37, the most prevailing structure type among the compounds within R–Ru(Os, Rh, Ir)–Ge systems is the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type. In addition to the compounds listed in table 37, the crystal structure has been solved for a few germanides with the  $\text{TiMnSi}_2$ -,  $\text{Sc}_2\text{CoSi}_2$ -,  $\text{Hf}_3\text{Ni}_2\text{Si}_3$ -,  $\text{CeNiSi}_2$ - and  $\text{BaNiSn}_3$ -types of structure. Morphotropic transformations were observed for the  $\text{RRuGe}$  compounds:  $(\text{La}–\text{Sm})\text{RuGe}$  (PbFCI structure type)  $\rightarrow$   $\text{HoRuGe}$  (TiNiSi structure type)  $\rightarrow$   $\text{ScRuGe}$  (ZrNiAl structure type).

Table 38  
Isotypic compounds of the ternary R–Pd(Pt)–Ge systems<sup>a</sup>

Structure type	La	Ce	Pr	Nd	Sm	Eu	Gd	Tb	Dy	Ho	Er	Tm	Yb	Lu	Y	Sc

	Pt	+	+	+	+	+		+	+	+	+	+	+	+		+
$\text{NdIrGe}_2$	Pt	–	+	+	+	+	–	+	+	+	+	+	+	+	–	+

<sup>a</sup>An empty cell means that the alloy of this composition was not investigated; a plus sign means that the compound exists, a minus sign that it was not observed.

The  $\text{RPt}_2\text{Ge}_2$  compounds crystallizes with two structure types,  $\text{CeGa}_2\text{Al}_2$  and  $\text{LaPt}_2\text{Ge}_2$  (see table 38). The  $\text{CePt}_2\text{Ge}_2$  compound has three polymorphic modifications,  $\text{CeGa}_2\text{Al}_2$ ,  $\text{CaBe}_2\text{Ge}_2$  and  $\text{LaPt}_2\text{Ge}_2$ . Compounds of equiatomic composition with platinum crystallize with the following structure types:  $\text{LaPtGe}$  (LaPtSi structure type)  $\rightarrow$   $(\text{Ce}–\text{Nd})\text{PtGe}$  ( $\text{KHg}_2$  structure type)  $\rightarrow$   $\text{SmPtGe}$  (TiNiSi structure type)  $\rightarrow$   $\text{EuPtGe}$  (ZrOS structure type)  $\rightarrow$   $(\text{Gd}–\text{Yb}, \text{Sc})\text{PtGe}$  (TiNiSi structure type).

#### 6.4. Peculiarities of the interactions in the R–R'–Ge systems

An analysis of the interaction of the components in the ternary systems R–R'–Ge for which the isothermal sections have been constructed showed that they can be divided into three groups: (a) systems which are characterized by formation of ternary compounds; (b) systems which are characterized by formation of continuous solid solutions and limited solid solutions between binary germanides; (c) systems in which both ternary compounds and continuous and limited solid solutions are formed.

(a) The Sc–Ce(Nd)–Ge ternary systems are characterized by the formation of ternary compounds, comparatively small solubility of the third component in the binary

compounds, and the absence of continuous solid solutions. These are connected with the significant differences in the rare-earth metal atom structure (absence of 4f electron shell in Sc atom) and in atom size ( $r_{\text{Sc}} = 0.164$  nm,  $r_{\text{Ce}} = 0.183$  nm,  $r_{\text{Nd}} = 0.182$  nm).

In comparing the considered systems with one another, it is necessary to indicate that at the transition from cerium to neodymium the number of ternary compounds decreases from 4 to 3 and the homogeneity range of the solid solutions on the base of the binary phases increases from 8 to 12.5 at.% Sc.

Concerning the formation of compounds, a common feature of these systems is the formation of the ternary phase with Ge content 33.3 at.% (ScRGe).

The  $\text{Ce}_{0.5}\text{Sc}_{4.5}\text{Ge}_4$  compound has no equivalent in the Nd–Sc–Ge system. The  $\text{R}_{1.25}\text{Sc}_3\text{Ge}_4$  compound exists with all the rare-earth metals of the cerium subgroup (La, Ce, Pr, Nd, Sm, Eu).

Considering the crystal structures of the compounds it is possible to conclude that the presence of scandium leads to the formation of various kinds of superstructures to the structure types of the binary compounds ( $\text{Sm}_5\text{Ge}_4$ ,  $\text{Ca}_2\text{As}$ ). RScGe ternary germanides are isostructural and are formed with the elements of the cerium subgroup (La, Ce, Pr, Nd, Sm, Eu), i.e. at the ratio  $r_{\text{R}}/r_{\text{Sc}}$  1.1; for R = Y, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu the compounds of this composition are not observed.

- (b) The existence of two components with close crystal chemical properties and a similar structure for most of the binary compounds determines the character of the interaction of the components in the Ce–La–Ge and Ce–Gd–Ge systems (absence of ternary compounds, formation of continuous and limited solid solutions between the isotypic binary compounds). As a consequence of the similar structure of all of the binary germanides, the Ce–La–Ge system is characterized by the formation of continuous solid solutions only (ratio  $r_{\text{Ce}}/r_{\text{La}} = 0.997$ ). In the Ce–Gd–Ge system, the isotypic compounds were found to form continuous solid solutions as well, and on the basis of compounds which belong to different structure types, limited substitutional solid solution of different extension were observed. Extension of the solid solutions by the substitution of one rare-earth element by another is determined by the size of substituting atoms.
- (c) The Sc–Y(Dy)–Ge and Ce–Y(Lu)–Ge systems occupy a special position among the R–R'–Ge systems. Both ternary compounds and continuous and limited solid solutions on the basis of binary compounds are found to exist. The peculiarity of the systems considered is the formation of continuous solid solutions between isostructural germanides with the composition  $\text{R}_5\text{Ge}_3$  ( $\text{Mn}_5\text{Si}_3$  structure type). One more continuous solid solution was observed in the system Ce–Y–Ge.

Another feature of the systems of this subgroup is the large extent of the limited solid solutions. Differences in the crystal chemistry characteristics of the rare-earth metals in the systems considered are insignificant, but they influence composition, structure and the number of ternary compounds. Ternary compounds with the composition  $\text{Sc}_{0.3}\text{R}_{0.7}\text{Ge}_2$  (R = Y, Dy) were found to exist for the Sc and Ge ternaries with Y and Dy on the digermanide section. They have no equivalent in other

R–R'–Ge systems. The formation of compounds with the  $Ce_{0.8}R_{0.2}Ge$  composition (structure type CrB) is characteristic of elements of the yttrium subgroup (Y, Dy, Ho, Er, Tm). An increase in the volume of the unit cell in the series of the isostructural compounds is connected with the ability of the cerium atoms to adopt an intermediate state.

As one can see from the present review, rare-earth metals show very similar crystal chemistry that is displayed in the formation of continuous solid solutions as well as substitutional solid solutions. On the other hand, differences in electron configuration of the rare-earth atoms influence the interactions in the ternary systems, as shown by different compositions, structures and the number of ternary compounds.

5. Discussion	327		
5.1. Classification of the ternary structure types of the germanides	328		

## Symbols and abbreviations

$a, b, c$	Unit cell dimensions (in nm)	R, R'	Y, Sc, and the lanthanides
$\alpha, \beta, \gamma$	Unit cell angles (in degrees)	$x$	indicate variable component contents, when it is used as index in compound compositional formula. Expressions like $N - x$ (where $N$ is a number) mean $N$ minus $x$ , with the $x$ value given in the text
$x/a, y/b, z/c$	Atomic coordinates		
SG	Space group		
$Z$	Number of formula units in a unit cell		
$G$ (%)	Occupation of crystallographic position		
at.%	Composition in atomic percent		
M, M'	s-, p-, d-element		

## 1. Introduction

The ternary systems of rare-earth metals with metallic and semimetallic components have been studied intensively during the last 20 years. Among them, the systems containing germanium are most completely investigated.

The preceding chapter (173) of this volume (Salamakha et al. 1999) is a review of ternary R–M–Ge systems which have been studied over the entire concentration region and which have been only partly investigated. The character of interaction in these systems varies, and major differences are seen in the number of ternary germanides observed within the investigated concentration range. This chapter is devoted to the description of the structure types and the crystal chemistry of the ternary (quaternary) germanides of the rare-earth metals.

The known structures of the germanides belong to 135 structure types. For each structure type the following information is presented:

- (i) chemical formula of the prototype;
- (ii) space group symbol and the number of formula units in the unit cell;
- (iii) lattice parameters (in nm) for the germanide (prototype or isotopic compound) on which the structure determination has been made and the appropriate reference;
- (iv) atomic positions and refined atomic coordinates; for compounds where statistical occupations of structure sites are observed, the various atoms are expressed as X, X1 etc. and additional data are presented;
- (v) projection of the structure and coordination polyhedra of the atoms;
- (vi) list of isotopic germanides; the unit cell dimensions and references for the isostructural compounds are presented in the preceding chapter (173) of this volume (Salamakha et al. 1999).

## 2. Influence of a third component on the fields of formation of ternary germanides

As R and Ge are components with much different crystallochemical properties (atomic size, electronic structure, electronegativity, etc.), the deciding factor that affects the formation, composition and structure, is the nature of the third component in the systems.

The ternary systems with two rare-earth metals and germanium are characterized by the formation of compounds with compositions  $(R, R')_5Ge_4$ ,  $(R, R')_{11}Ge_{10}$ ,  $(R, R')Ge$  and  $(R, R')_2Ge$  which crystallize with the structure types of binary compounds and their superstructures. This is caused by the similarities in the electronic structure of R elements.

When the third component is a p element (Al, Ga, In, Si, Sn, Sb, Bi), the trends in formation of compounds are found to be maintained in the same R to Ge ratio as in the binary compounds. The compounds are characterized by a variable composition at constant R content, but in contrast to the R-R'-Ge systems, the compositions of compounds are more varied (fig. 1).

The main reason for the formation of a large number of ternary compounds in the R-M-Ge systems (M=s or d element) is the presence of components with significantly different crystallochemical properties (fig. 2).

Figures 1 and 2 presents only the compositions of compounds in which the crystal structure has been determined. In many cases, the substitution of a M component or a change in temperature leads to the formation of another structure (these compositions are marked with a square). In spite of the variety of compositions, one can see from fig. 2 that the predominant number of compounds are arranged on the lines connecting the elements with the binary phases of simple compositions (R-MGe, R-MGe<sub>2</sub> etc.).

The most favourable concentration for the formation of intermetallic compounds is 33 at.% of R ( $RM_2$ -RGe<sub>2</sub>), particularly the composition RMGe. The compounds of equatomic composition crystallize in 20 structure types. The morphotropic transformation within the RMGe series occurs both if R is replaced by another R', and when the M component is changed.

Fig. 1. Composition triangle showing the existence of ternary compounds in the R-M-Ge systems when M is p-element.

Fig. 2. Composition triangle showing the existence of ternary compounds in the R-M-Ge systems when M is s- and d-element.

For a better demonstration of the influence of the R component on the formation of ternary germanides and their crystal chemistry, and for the improvement and simplification of the presentation of the crystallographic data of the compounds, we have characterised the composition of a given phase according to its  $R/(M, Ge)$  ratio, and arranged the structure types according to increasing rare-earth content in the next section of this chapter.

The same approach is used for the description of the quaternary germanides (sect. 4 of the present review). However, the literature data on the crystal structures of quaternary germanides are quite sparse.

### 3. Structure types of ternary rare-earth germanides

#### 3.1. $R(M,Ge)_{13}$ compounds

##### 3.1.1. $NaZn_{13}$ structure type

SG Fm3c,  $Z=8$ ,  $a=1.1371$  for  $La(Ni_{0.82}Ge_{0.18})_{13}$  (Bruskov 1984)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
La	8(a)	1/4	1/4	1/4	100
X1	8(b)	0	0	0	100
X2	96(i)	0	0.1782	0.1151	100

$X=0.82Ni+0.18Ge$

No isotypic compounds are known.

##### 3.1.2. $CeNi_{8.5}Si_{4.5}$ structure type

SG I4/mcm,  $Z=4$ ,  $a=0.7932$ ,  $c=1.1817$  for  $Pr_{1-x}Co_xGe_4$  (Fedyna et al. 1987)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Pr	4(a)	0	0	1/4	69.3
Co1	16(l)	0.1815	0.6815	0.1284	100
Co2	16(l)	0.6273	0.1273	0.1668	100
Co3	4(d)	0	1/2	0	100
Ge	16(k)	0.0633	0.2002	0	100

Isotypic compounds:

$RNi_{8.5}Ge_{4.5}$ : R = Ce, Pr, Nd, Sm, Eu

\* In the  $RNi_{8.5}Ge_{4.5}$  compounds the site in Wyckoff position 4(d) is occupied by a statistical mixture  $Ni_{0.5}Ge_{0.5}$ .

The praseodymium atoms have coordination number 24 (fig. 3a). Coordination polyhedra for cobalt and germanium are the icosahedra and their derivatives (fig. 3b–e).

Fig. 3. Projection of the  $\text{Pr}_{1-x}\text{Co}_3\text{Ge}_4$  unit cell and coordination polyhedra of the atoms: (a) Pr, (b–e) Co, Ge.

### 3.2. $R(M, \text{Ge})_{12}$ compounds

#### 3.2.1. $\text{YCo}_6\text{Ge}_6$ structure type

SG P6/mmm,  $Z = 1$ ,  $a = 0.5074$ ,  $c = 0.3908$  for  $\text{YCo}_6\text{Ge}_6$  (Buchholz and Schuster 1981)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Y	1(a)	0	0	0	45
Co	3(g)	1/2	0	1/2	100
Ge1	2(e)	0	0	0.307	50
Ge2	2(c)	1/3	2/3	0	100

Isotypic compounds:

$\text{RMn}_6\text{Ge}_6$ : R = Nd, Sm

$\text{RFe}_6\text{Ge}_6$ : R = Y, Pr–Sm, Gd–Lu

$\text{RCo}_6\text{Ge}_6$ : R = Y, Sc, Gd–Lu

For yttrium atoms, polyhedra with 20 apexes are typical (fig. 4a). Those for cobalt and germanium atoms are the icosahedra and their derivatives (fig. 4b–d).

#### 3.2.2. $\text{MgFe}_6\text{Ge}_6$ (or $\text{HfFe}_6\text{Ge}_6$ ) structure type

SG P6/mmm,  $Z = 1$ ,  $a = 0.52262$ ,  $c = 0.81653$  for  $\text{DyMn}_6\text{Ge}_6$  (Schöbinger-Papamantellos et al. 1994)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Dy	1(a)	0	0	0	100

Fig. 4. Projection of the  $\text{YCo}_6\text{Ge}_6$  unit cell and coordination polyhedra of the atoms: (a) Y, (b-d) Co and Ge.

Mn	6(i)	1/2	0	0.2504	100
Ge1	2(e)	0	0	0.3453	100
Ge2	2(d)	1/3	2/3	1/2	100
Ge3	2(c)	1/3	2/3	0	100

Isotypic compounds:

$\text{RCr}_6\text{Ge}_6$ : R = Sc, Y, Tb–Er

$\text{RMn}_6\text{Ge}_6$ : R = Sc, Y, Gd–Lu

$\text{RFe}_6\text{Ge}_6$ : R = Sc, Yb, Lu

The coordination polyhedra for dysprosium atoms have 20 apexes (fig. 5a). For manganese and germanium atoms, icosahedra and their derivatives are typical (fig. 5b–e).

### 3.2.3. $\text{GdMn}_6\text{Ge}_6$ structure type

SG  $\text{P6}/\text{mmm}$ ,  $Z = 1$ ,  $a = 0.52333$ ,  $c = 0.81806$  (Belyavina et al. 1993)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Gd1	1(a)	0	0	0	70
Gd2	1(b)	0	0	1/2	30
Mn	6(i)	1/2	0	0.25	100
Ge1	2(e)	0	0	0.3465	100
Ge2	2(d)	1/3	2/3	1/2	100
Ge3	2(c)	1/3	2/3	0	100

No isotypic compounds are observed.

Fig. 5. Projection of the  $\text{DyMn}_6\text{Ge}_6$  unit cell and coordination polyhedra of the atoms: (a) Dy, (b–e) Mn and Ge.

### 3.2.4. $\text{ScNi}_6\text{Ge}_6$ structure type

SG  $\text{P6}/\text{mmm}$ ,  $Z=4$ ,  $a=1.0152$ ,  $c=0.7813$  for  $\text{ScNi}_6\text{Ge}_6$  (Buchholz and Schuster 1981)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Sc1	3(g)	1/2	0	1/2	100
Sc2	1(a)	0	0	0	100
Ni1	12(o)	0.247	0.494	0.250	100
Ni2	12(n)	0.238	0	0.258	100
Ge1	6(m)	0.162	0.324	1/2	100
Ge2	6(l)	0.160	0.320	0	100
Ge3	6(i)	1/2	0	0.158	100
Ge4	2(e)	0	0	0.340	100
Ge5	2(d)	1/3	2/3	1/2	100
Ge6	2(c)	1/3	2/3	0	100

No isotypic compounds are observed.

### 3.2.5. $\text{GdFe}_6\text{Ge}_6$ structure type

SG  $\text{Pnma}$ ,  $a=6.143$ ,  $b=0.8137$ ,  $c=7.979$  (Venturini et al. 1992)

Atomic coordinates have not been determined.

### 3.2.6. $TbFe_6Sn_6$ structure type

SG Cmc $\bar{m}$ ,  $Z=4$ ,  $a=0.8116$ ,  $b=1.7672$ ,  $c=0.5120$  for  $YFe_6Ge_6$  (Venturini et al. 1992)

Atomic coordinates for the germanides of this structure type have not been determined.

Isotypic compounds:

$RFe_6Ge_6$ :  $R = Tb-Ho$

### 3.2.7. $HoFe_6Sn_6$ structure type

SG Immm,  $Z=6$ ,  $a=0.8103$ ,  $b=2.652$ ,  $c=0.5108$  for  $ErFe_6Ge_6$  (Venturini et al. 1992)

Atomic coordinates for the germanides of this structure type have not been determined.

Isotypic compound:  $RFe_6Ge_6$ :  $R = Tm$

## 3.3. $R_3(M, Ge)_{34}$ and $R_3(M, Ge)_{26}$ compounds

### 3.3.1. $Ce_3Pt_{23}Ge_{11}$ structure type

SG  $F\bar{4}3m$ ,  $Z=8$ ,  $a=1.71833$  for  $Ce_3Pt_{23}Ge_{11}$  (Gribanov et al. 1993a). See fig. 6.

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Ce	24(g)	0.0018	1/4	1/4	100
Pt1	48(h)	0.0841	0.0841	0.2479	100

Fig. 7. Projection of the  $\text{Ce}_3\text{Pd}_{20}\text{Ge}_6$  unit cell and coordination polyhedra of the atoms: (a,b) Ce, (c,d) Pd, (e) Ge.

Pd2	48(h)	0	0.17479	0.17479	100
Ge	24(e)	0.2325	0	0	100

Isotypic compounds:

$\text{R}_3\text{Pd}_{20}\text{Ge}_6$ : R=Nd, Sm

### 3.4. $\text{R}_2(\text{M},\text{Ge})_{17}$ compounds

#### 3.4.1. $\text{Th}_2\text{Zn}_{17}$ structure type

SG  $\text{R}\bar{3}\text{m}$ ,  $Z=3$ ,  $a=0.8425\text{--}0.8433$ ,  $c=1.2336\text{--}1.2368$  for  $\text{Sm}_2\text{Co}_{15.1\text{--}14.1}\text{Ge}_{1.9\text{--}2.9}$  (Mruz 1988).

Atomic coordinates for this compound have not been determined.

#### 3.4.2. $\text{Ce}_2\text{Al}_2\text{Co}_{15}$ structure type

SG  $\text{R}\bar{3}\text{m}$ ,  $Z=3$ ,  $a=0.9021$ ,  $c=1.3787$  for  $\text{Ce}_2\text{Zn}_{15}\text{Ge}_2$  (Opainych 1996)

Atomic coordinates for this compound have not been determined.

#### 3.4.3. $\text{Nd}_2\text{Cr}_9\text{Ge}_8$ structure type

SG  $\text{Pmma}$ ,  $Z=2$ ,  $a=0.9388$ ,  $b=0.4046$ ,  $c=0.8045$  (Bodak et al. 1989a)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Nd	2(e)	1/4	0	0.6680	100

Cr1	4(i)	0.1064	0	0.2973	100
Cr2	2(f)	1/4	1/2	0.0516	50
Cr3	2(d)	0	1/2	1/2	100
Cr4	2(a)	0	0	0	100
Ge1	4(k)	1/4	0.1587	0.0419	50
Ge2	4(j)	0.5387	1/2	0.1787	100
Ge3	2(f)	1/4	1/2	0.3780	100

No isotopic compounds are observed.

Fig. 8. Projection of the  $\text{Nd}_2\text{Cr}_9\text{Ge}_8$  unit cell and coordination polyhedra of the atoms: (a) Nd, (b-e) Cr, (f-h) Ge.

For neodymium atoms, polyhedra with 18 apexes are typical (fig. 8a). The chromium atom polyhedra are distorted cubo-octahedra and pentagonal prisms with additional atoms (fig. 8b-e). Those for germanium atoms are polyhedra with 11 apexes and pentagonal prisms with additional atoms (fig. 8f-h).

3.5.  $R(M, Ge)_8$  compounds3.5.1.  $YNi_5Si_3$  structure typeSG Pnma,  $Z=4$ ,  $a=1.90183$ ,  $b=0.38398$ ,  $c=0.67867$  for  $TmNi_5Ge_3$  (Fedyna 1988)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Tm	4(c)	0.3542	1/4	0.878	100
Ni1	4(c)	0.0021	1/4	0.390	100
Ni2	4(c)	0.2070	1/4	0.067	100
Ni3	4(c)	0.2008	1/4	0.691	100
Ni4	4(c)	0.3854	1/4	0.365	100
Ni5	4(c)	0.4864	1/4	0.591	100
Ge1	4(c)	0.0765	1/4	0.645	100
Ge2	4(c)	0.0884	1/4	0.090	100
Ge3	4(c)	0.2598	1/4	0.380	100

Isotypic compounds:

 $RNi_5Ge_3$ :  $R=Y, Gd-Lu$ 

The coordination polyhedra for thulium atoms have 20 apexes (fig. 9a). The nickel atoms are situated inside polyhedra with 12 and 15 apexes (fig. 9b–f). For germanium atoms, trigonal prisms with three additional atoms are typical (fig. 9g–i).

Fig. 9. Projection of the  $TmNi_5Ge_3$  unit cell and coordination polyhedra of the atoms: (a) Tm, (b–f) Ni, (g–i) Ge.

3.5.2.  $YCo_5P_3$  structure type

SG Pnma,  $Z=4$ ,  $a=1.3050$ ,  $b=0.3904$ ,  $c=1.1408$  for  $TbMn_5Ge_3$  (Venturini and Malaman 1997)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Tb	4(c)	0.2068	1/4	0.9131	100
Mn1	4(c)	0.4807	1/4	0.7923	100
Mn2	4(c)	0.9986	1/4	0.0888	100
Mn3	4(c)	0.6852	1/4	0.2941	100
Mn4	4(c)	0.1879	1/4	0.6180	100
Mn5	4(c)	0.4366	1/4	0.0338	100
Ge1	4(c)	0.6211	1/4	0.0887	100
Ge2	4(c)	0.3766	1/4	0.2406	100
Ge3	4(c)	0.8796	1/4	0.9125	100

No isotypic compounds are observed.

3.6.  $R(M, Ge)_6$  compounds3.6.1.  $ZrFe_4Si_2$  structure type

SG  $P4_2/mnm$ ,  $Z=2$ ,  $a=0.72472$ ,  $c=0.38705$  for  $TmFe_4Ge_2$  (Fedyna 1988)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Tm	2(a)	0	0	0	100
Fe	8(i)	0.086	0.353	0	100
Ge	4(f)	0.215	0.215	1/2	100

Isotypic compounds:

$RFe_4Ge_2$ : R = Y, Dy–Lu

$RCo_4Ge_2$ : R = Er–Lu

Thulium atoms are situated inside the polyhedra with 20 apexes (fig. 10a). The coordination polyhedra of iron atoms are deformed cubo-octahedra (fig. 10b). The germanium atoms have an environment in a form of trigonal prism with three additional atoms (fig. 10c).

Fig. 10. Projection of the  $\text{TmFe}_2\text{Ge}_2$  unit cell and coordination polyhedra of the atoms: (a) Tm, (b) Fe, (c) Ge.

### 3.6.2. $\text{SmNi}_3\text{Ge}_3$ structure type

SG  $I4/mmm$ ,  $Z=4$ ,  $a=0.40659$ ,  $c=2.5137$  (Mruz et al. 1990)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Sm	4(e)	0	0	0.3465	100
Ni1	8(g)	0	1/2	0.0553	100
Ni2	4(e)	0	0	0.1999	100
Ge1	4(e)	0	0	0.1063	100
Ge2	4(d)	0	1/2	1/4	100
Ge3	2(b)	0	0	1/2	100
Ge4	2(a)	0	0	0	100

No isotopic compounds are observed.

The coordination numbers for the Sm atoms are 22 (fig. 11a). The coordination polyhedra for the Ni atoms are tetragonal antiprisms with one additional atom and distorted cubo-octahedra with one additional apex (fig. 11b,c); those for Ge atoms are tetragonal antiprisms with two additional atoms and distorted cubo-octahedra with two additional apexes (fig. 11d-g).

Fig. 11. Projection of the  $\text{SmNi}_3\text{Ge}_3$  unit cell and coordination polyhedra of the atoms: (a) Sm, (b-c) Ni, (d-g) Ge.

### 3.6.3. $\text{EuMg}_3\text{Ge}_3$ structure type

SG  $\text{Cmcm}$ ,  $Z=4$ ,  $a=0.4485$ ,  $b=3.060$ ,  $c=0.4485$  (Zmii et al. 1973)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Eu	4(c)	0	0.442	1/4	100
Mg1	4(c)	0	0.650	1/4	100
Mg2	4(c)	0	0.750	1/4	100
Mg3	4(c)	0	0.855	1/4	100
Ge1	4(c)	0	0.017	1/4	100
Ge2	4(c)	0	0.098	1/4	100
Ge3	4(c)	0	0.303	1/4	100

No isotypic compounds are observed.

Fig. 12. Projection of the  $\text{EuMg}_3\text{Ge}_3$  unit cell and coordination polyhedra of the atoms: (a) Eu, (b-d) Mg, (e-g) Ge.

The coordination polyhedra for europium atoms have 20 apexes (fig. 12a). Magnesium atoms are situated in the centre of the tetragonal prisms with additional atoms (fig. 12b, c)

and trigonal prisms with additional atoms (fig. 12d). Coordination polyhedra in the form of trigonal prism, tetragonal antiprism and cubo-octahedra are typical for the germanium atoms (fig. 12e–g).

### 3.7. $R_3(M, Ge)_{17}$ compounds

#### 3.7.1. $Yb_3Rh_4Sn_{13}$ structure type

SG  $Pm\bar{3}n$ ,  $Z=2$ ,  $a=0.8962$  for  $Y_3Ru_4Ge_{13}$  (Segre et al. 1981). See fig. 13.

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Y	6(c)	1/4	0	1/2	100
Ru	8(e)	1/4	1/4	1/4	100
Ge1	24(k)	0	0.15333	0.30570	100
Ge2	2(a)	0	0	0	100

Isotypic compounds:

$R_3Co_4Ge_{13}$ : R = Y, Sm, Gd–Lu

$R_3Ru_4Ge_{13}$ : R = Y, Ce–Sm, Gd–Lu

$R_3Rh_4Ge_{13}$ : R = Y, Nd, Sm, Gd–Lu

$R_3Os_4Ge_{13}$ : R = Y, Ce–Sm, Gd–Lu

$R_3Ir_4Ge_{13}$ : R = Y, Ce–Sm, Gd–Lu

Fig. 13. Projection of the  $Y_3Ru_4Ge_{13}$  unit cell and coordination polyhedra of the atoms: (a) Y, (b) Ru, (c, d) Ge.

Fig. 14. Two types of unit cells in the  $Y_3Co_4Ge_{13}$  structure and coordination polyhedra of the atoms.

### 3.7.2. $Y_3Co_4Ge_{13}$ structure type

SG  $Pm\bar{3}n$ ,  $Z=2$ ,  $a=0.8769$  (Bruskov et al. 1986). See fig. 14.

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Y	6(c)	1/4	0	1/2	100
Co	8(e)	1/4	1/4	1/4	100

Ge1	24(k)	0	0.142	0.273	42
Ge2	24(k)	0	0.161	0.327	58
Ge3	2(a)	0	0	0	100

This structure type differs from the  $\text{Yb}_3\text{Rh}_4\text{Sn}_{13}$  type by the splitting of the site in Wyckoff position 24(k).

Isotypic compounds:

$\text{R}_3\text{Co}_4\text{Ge}_{13}$ : R = Y, Gd–Lu

$\text{R}_3\text{Ru}_4\text{Ge}_{13}$ : R = Ce, Nd

$\text{R}_3\text{Os}_4\text{Ge}_{13}$ : R = Nd, Ho

### 3.8. $\text{R}_2(\text{M}, \text{Ge})_{11}$ compounds

#### 3.8.1. $\text{Ce}_2\text{Pt}_7\text{Ge}_4$ structure type

SG Pnma,  $Z=4$ ,  $a=1.9866$ ,  $b=0.4089$ ,  $c=1.1439$  (Gribanov et al. 1992a)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Ce1	4(c)	0.0281	1/4	0.7437	100
Ce2	4(c)	0.2199	1/4	0.5122	100
Pt1	4(c)	0.0351	1/4	0.0604	100
Pt2	4(c)	0.0412	1/4	0.4534	100

Ge5	2(a)	1/4	1/4	0.2352	100

Isotypic compounds:

 $R_4Rh_{13}Ge_9$ ; R = Y, La–Sm, Gd–Lu $R_4Ir_{13}Ge_9$ ; R = Y, La–Sm, Gd–Lu

The coordination polyhedra of the holmium atoms have 20 apexes (fig. 16a–c). Those of iridium are tetragonal prisms with five additional atoms and distorted cubo-octahedra (fig. 16d–k). The coordination polyhedra of germanium atoms are trigonal prisms with three additional atoms (fig. 16l–q).

Fig. 16. Projection of the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$  unit cell and coordination polyhedra of the atoms: (a-c) Ho, (d-k) Ir, (l-q) Ge.

### 3.9. $R(M, \text{Ge})_5$ compounds

#### 3.9.1. $\text{CaCu}_5$ structure type

SG  $P6/mmm$ ,  $Z=1$ ,  $a=0.5296$ ,  $c=0.4413$  for  $\text{SmPt}_{4.4}\text{Ge}_{0.6}$  (Barakatova 1994)

Atomic coordinates for this compound have not been determined.

#### 3.9.2. $\text{Sc}_3\text{Ni}_{11}\text{Si}_4$ structure type

SG  $P6_3/mmc$ ,  $Z=2$ ,  $a=0.8321$ ,  $c=0.8832$  for  $\text{Tm}_3\text{Ni}_{11}\text{Ge}_4$  (Fedyna 1988). See fig. 17.

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Tm	6(h)	0.1883	0.3766	1/4	100
Ni1	12(k)	0.1719	0.344	0.594	100
Ni2	6(h)	0.537	0.075	1/4	100
Ni3	4(f)	1/3	2/3	0.073	100
Ge1	6(g)	1/2	0	0	100
Ge2	2(b)	0	0	1/4	72

Isotypic compounds:

$\text{R}_3\text{Ni}_{11}\text{Ge}_4$ : R = Tb-Lu, Y

Fig. 17. Projection of the  $Tm_3Ni_{11}Ge_4$  unit cell and coordination polyhedra of the atoms: (a) Tm, (b–d) Ni, (e, f) Ge.

### 3.9.3. $Sc_3Ni_{11}Ge_4$ structure type

SG  $P6_3/mmc$ ,  $Z=2$ ,  $a=0.8130$ ,  $c=0.8505$  (Andrusyak 1988)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Sc	6(h)	0.190	0.380	1/4	100
Ni1	12(k)	0.162	0.324	0.581	100
Ni2	6(h)	0.555	0.110	1/4	100

Ge1	6(g)	1/2	0	0	100
Ge2	2(b)	0	0	1/4	72
Ge3	2(a)	0	0	0	28

No isotypic compounds are observed.

The 2(a) atomic position, which is partly occupied in this structure, is vacant in the previous structure type.

### 3.9.4. $ErNi_3Ge_2$ structure type

SG  $P\bar{6}$ ,  $Z=12$ ,  $a=1.79662$ ,  $c=0.37941$  (Oleksyn and Bodak 1994). See fig. 18.

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Er1	3(k)	0.0088	0.5756	1/2	100
Er2	3(k)	0.0969	0.3366	1/2	100

Ge6	2(b)	1/2	1/2	0	100
Ge7	2(a)	0	0	0	100

No isotopic compounds have been observed.

3.10.2.  $Nb_2Cr_4Si_5$  structure type

SG Ibam,  $Z=4$ ,  $a=0.7821$ ,  $b=1.6662$ ,  $c=0.5146$  for the  $Sc_2Cr_4Ge_5$  compound (Andrusyak 1988)

Atomic coordinates have not been determined.

3.11.  $R(M, Ge)_4$  compounds3.11.1.  $CeGa_2Al_2$  structure typeSG I4/mmm,  $Z=2$ ,  $a=0.4042$ ,  $c=1.0183$  for  $NdCo_2Ge_2$  (Salamakha 1989)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Nd	2(a)	0	0	0	100
Co	4(d)	0	1/2	1/4	100
Ge	4(e)	0	0	0.387	100

Isotypic compounds:

 $RMn_2Ge_2$ : R = Y, La–Sm, Gd–Yb $RFe_2Ge_2$ : R = Y, La–Sm, Gd–Lu $RCO_2Ge_2$ : R = Y, La–Yb $RNi_2Ge_2$ : R = Y, La–Lu $RCu_2Ge_2$ : R = Y, La–Yb $RRu_2Ge_2$ : R = Y, La–Lu $RRh_2Ge_2$ : R = Y, La–Lu $RPd_2Ge_2$ : R = Y, La–Lu $RAg_2Ge_2$ : R = La–Gd $RPt_2Ge_2$ : R = Y, La–Dy, Er $RAu_2Ge_2$ : R = Ce, Nd

For neodymium atoms, polyhedra with 22 apexes are typical (fig. 19a). The cobalt atom polyhedra are distorted cubo-octahedra (fig. 19b). Tetragonal antiprisms with one additional atom are typical for germanium atoms (fig. 19c).

Fig. 19. Projection of the  $NdCo_2Ge_2$  unit cell and coordination polyhedra of the atoms: (a) Nd, (b) Co, (c) Ge.

3.11.2.  $\text{CaBe}_2\text{Ge}_2$  structure typeSG  $P4/nmm$ ,  $Z=2$ ,  $a=0.4246$ ,  $c=1.0098$  for  $\text{CeIr}_2\text{Ge}_2$  (Mathur and Frost 1994)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Ce	2(c)	1/4	1/4	0.749	100

Ge3	4(e)	0	0.5071	1/4	100
Ge4	4(e)	0	0.7796	1/4	100

Isotypic compounds:

$\text{R}_2\text{Co}_3\text{Ge}_5$ : R = Pr–Sm, Gd–Er

$\text{R}_2\text{Rh}_3\text{Ge}_5$ : R = Nd–Sm, Gd–Tm

Fig. 24. Projection of the  $\text{Ho}_2\text{Rh}_3\text{Ge}_5$  unit cell and coordination polyhedra of the atoms: (a) Ho, (b,c) Rh, (d-g) Ge.

### 3.11.7. $\text{SmNiGe}_3$ structure type

SG Cmmm,  $Z=4$ ,  $a=0.4102$ ,  $b=2.1657$ ,  $c=0.4092$  (Bodak et al. 1985)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Sm	4(j)	0	0.3318	1/2	100
Ni	4(i)	0	0.1092	0	100
Ge1	4(j)	0	0.0568	1/2	100
Ge2	4(i)	0	0.2164	0	100
Ge3	4(i)	0	0.4433	0	100

Isotypic compounds:

$\text{RNiGe}_3$ : R = Y, Ce–Sm, Gd–Tm

$\text{RGaGe}_3$ : R = Y, Gd

The coordination polyhedra with 20 apexes are typical for samarium atoms (fig. 25a). Those for nickel atoms are tetragonal antiprisms (fig. 25b). The germanium coordination polyhedra are trigonal prisms (fig. 25c–e).

Fig. 25. Projection of the  $\text{SmNiGe}_3$  unit cell and coordination polyhedra of the atoms: (a) Sm, (b) Ni, (c-e) Ge.

### 3.11.8. $\text{BaNiSn}_3$ structure type

SG  $I4mm$ ,  $Z=2$ ,  $a=0.4350$ ,  $c=0.9865$  for  $\text{LaCoGe}_3$  (Venturini et al. 1985)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
La	2(a)	0	0	0.5759	100
Co	2(a)	0	0	0.2313	100
Ge1	2(a)	0	0	0.0000	100
Ge2	4(b)	0	1/2	0.3253	100

Isotypic compounds:

$\text{RCoGe}_3$ : R = Ce–Eu, Yb

$\text{RRhGe}_3$ : R = La–Pr, Eu

$\text{RIrGe}_3$ : R = La, Eu

$\text{RRuGe}_3$ : R = La

$\text{ROsGe}_3$ : R = La

The coordination number of lanthanum atoms is 21 (fig. 26a). Cobalt atoms have the coordination polyhedra in a form of tetragonal antiprisms (fig. 26b). Germanium atoms are situated inside the tetragonal antiprisms and distorted cubo-octahedra (fig. 26c, d).

## 3.12. $R_2(M, \text{Ge})_7$ compounds

### 3.12.1. $\text{Ba}_2\text{Cd}_3\text{Bi}_4$ structure type

SG  $Cmca$ ,  $Z=4$ ,  $a=0.6143$ ,  $b=1.5193$ ,  $c=0.8035$  for  $\text{La}_2\text{Al}_3\text{Ge}_4$  (Zhao and Parthé 1991c). See fig. 27.

Ge3	4(g)	0.0669	0.5669	0	100

Isotypic compounds:

$R_5Co_4Ge_{10}$ : R = Tm–Lu

$R_5Rh_4Ge_{10}$ : R = Y, Gd–Lu

$R_5Os_4Ge_{10}$ : R = Y, Dy–Tm

The coordination numbers for holmium atoms are 17, 18 and 20 (fig. 46a–c). Rhodium atoms have coordination polyhedra in the form of trigonal prisms with four additional atoms (fig. 46d). Germanium atoms are situated inside the trigonal prisms with three additional atoms and deformed cubo-octahedra (fig. 46e–g).

Fig. 46. Projection of the  $\text{Ho}_3\text{Rh}_4\text{Ge}_{10}$  unit cell and coordination polyhedra of the atoms: (a-c) Ho, (d) Rh, (e-g) Ge.

### 3.15.2. $\text{Zr}_4\text{Co}_4\text{Ge}_7$ structure type

SG 14/mmm,  $Z=4$ ,  $a=1.3215$ ,  $c=0.5229$  for  $\text{Sc}_4\text{Co}_4\text{Ge}_{7-x}$  (Andrusyak 1988). See fig. 47.

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Sc1	8(i)	0.1966	0	0	100

Isotypic compounds:

$\text{Sc}_4\text{M}_4\text{Ge}_{7-x}$ : M=Fe, Ni

Fig. 47. Projection of the  $\text{Sc}_4\text{Co}_4\text{Ge}_7$  unit cell and coordination polyhedra of the atoms: (a, b) Sc, (c) Co, (d–g) Ge.

### 3.15.3. $\text{La}_4\text{Ga}_4\text{Ge}_7$ structure type

SG Pmmm,  $a=0.8414$ ,  $b=0.8620$ ,  $c=3.109$  for  $\text{Ce}_4\text{Ga}_4\text{Ge}_7$  (Gryniv et al. 1989)

Atomic coordinates for the germanides of this structure type were not presented.

Isotypic compounds:

$\text{R}_4\text{Ga}_4\text{Ge}_7$ : R = La, Nd

### 3.16. $\text{R}_3(\text{M}, \text{Ge})_8$ compounds

#### 3.16.1. $\text{Gd}_3\text{Cu}_4\text{Ge}_4$ structure type

SG Immm,  $Z=2$ ,  $a=0.4223$ ,  $b=0.6655$ ,  $c=1.4000$  (Rieger 1970)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Gd1	4(j)	1/2	0	0.36884	100
Gd2	2(a)	0	0	0	100
Cu	8(l)	0	0.31067	0.33048	100

Ge1	4(i)	0	0	0.21567	100
Ge2	4(h)	0	0.18902	1/2	100

Isotypic compounds:

$R_3Mn_4Ge_4$ : R = Gd, Tb

$R_3Fe_4Ge_4$ : R = Dy–Tm, Lu

$Sc_3Ni_4Ge_4$

$R_3Cu_4Ge_4$ : R = Sc, Y, Pr–Sm, Gd–Lu

$R_3Ag_4Ge_4$ : R = Pr–Sm, Gd

$R_3Pd_4Ge_4$ : R = Y, Gd–Tm

The coordination numbers for the Gd atoms are 20 and 19 (fig. 48a, b). The coordination polyhedra for the Cu atoms are distorted cubo-octahedra (fig. 48c); those for Ge atoms are trigonal prisms with additional atoms (fig. 48d, e).

Fig. 48. Projection of the  $Gd_3Cu_4Ge_4$  unit cell and coordination polyhedra of the atoms: (a, b) Gd, (c) Cu, (d, e) Ge.

### 3.16.2. $U_3Ni_4Si_4$ structure type

SG Immm,  $Z=2$ ,  $a=0.42234$ ,  $b=0.42295$ ,  $c=2.4156$  for  $La_3Ni_4Ge_4$  (Bruskov 1984)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)

### 3.19. $R(M, \text{Ge})_2$ compounds

#### 3.19.1. $\text{ZrSi}_2$ structure type

SG Cmc $\bar{m}$ ,  $Z=4$ ,  $a=0.4502$ ,  $b=1.5367$ ,  $c=0.4502$  for  $\text{SmSn}_{1.5}\text{Ge}_{0.5}$  (Stetskiv 1999). See fig. 53.

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Sm	4(c)	0	0.0811	1/4	100
X	4(c)	0	0.4280	1/4	100
X	4(c)	0	0.7579	1/4	100

$X=0.25\text{Ge}+0.75\text{Sn}$

Isotypic compounds:

$\text{RSn}_{1.5}\text{Ge}_{0.5}$ : R = La–Pr

#### 3.19.2. $\text{MgZn}_2$ structure type

SG  $\text{P}6_3/\text{mmc}$ ,  $Z=4$ ,  $a=0.5006$ ,  $c=0.8150$  for  $\text{Sc}_2\text{Fe}_3\text{Ge}$  (Andrusyak 1988)

Atomic coordinates have not been determined.

#### 3.19.3. $\text{MgCu}_2$ structure type

SG  $\text{Fd}3\text{m}$ ,  $Z=8$ ,  $a=0.7063$  for  $\text{Sc}(\text{Sc}, \text{Fe}, \text{Ge})_2$  (Andrusyak 1988)

Atomic coordinates have not been determined.

#### 3.19.4. $\text{Y}_2\text{Rh}_3\text{Ge}$ structure type

SG  $\text{R}\bar{3}\text{m}$ ,  $Z=3$ ,  $a=0.5552$ ,  $c=1.182$  for  $\text{Y}_2\text{Rh}_3\text{Ge}$  (Cenzual et al. 1987)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Y	6(c)	0	0	0.3718	100

Rh	9(d)	1/2	0	1/2	100
Ge	3(a)	0	0	0	100

Isotypic compounds:

$R_2Rh_3Ge$ : R = Pr, Er

### 3.19.5. $PbFCl$ structure type

SG  $P4/nmm$ ,  $Z=2$ ,  $a=0.4170$ ,  $c=0.6865$  for  $CeCoGe$  (Welter et al. 1993)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Ce	2(c)	1/4	1/4	0.67	100
Co	2(a)	3/4	1/4	0	100
Ge	2(c)	1/4	1/4	0.19	100

Isotypic compounds:

$RTiGe$ : R = Y, Gd–Tm

$RMnGe$ : R = La–Sm

$CeFeGe$

$RCoGe$ : R = La–Nd

$RRuGe$ : R = La–Sm

For cerium atoms, polyhedra with 18 apexes are typical (fig. 54a). The cobalt atom polyhedra are distorted cubo-octahedra (fig. 54b). Those for germanium atoms are tetragonal antiprisms with one additional atom (fig. 54c).

Fig. 54. Projection of the  $CeCoGe$  unit cell and coordination polyhedra of the atoms: (a) Ce, (b) Co, (c) Ge.

3.19.6. *CeScSi* structure typeSG I4/mmm,  $Z=4$ ,  $a=0.4314$ ,  $c=1.5913$  for CeScGe (Shpyrka 1990)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Ce	4(e)	0	0	0.326	100
Sc	4(c)	0	1/2	0	100
Ge	2(e)	0	0	0.124	100

Isotypic compounds:

RScGe: R=La–Eu

Fig. 55. Projection of the CeScGe unit cell and coordination polyhedra of the atoms: (a) Ce, (b) Sc, (c) Ge.

The coordination polyhedra for cerium atoms have 17 apexes (fig. 55a). Scandium atoms are situated in the centres of the cubo-octahedra (fig. 55b). The coordination polyhedra in the form of tetragonal antiprism with one additional atom are typical for the germanium atoms (fig. 55c).

3.19.7. *AlB<sub>2</sub>* structure typeSG P6/mmm,  $Z=1$ ,  $a=0.4277$ ,  $c=0.3881$  for NdCuGe (Salamakha 1986)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Nd	1(a)	0	0	0	100
X	2(d)	1/3	2/3	1/2	100

 $X=0.5\text{Cu}+0.5\text{Ge}$

Isotypic compounds:

Ag	2(b)	1/3	2/3	0.2514	100
Ge	2(b)	1/3	2/3	0.7082	100

Isotypic compounds:

RAgGe: R = Ce, Pr

RAuGe: R = Sc, Y, La–Sm, Gd–Lu

The coordination polyhedra of the lanthanum atoms have 14 apexes (fig. 57a). Those for silver and germanium atoms are trigonal prisms with additional atoms (fig. 57b,c).

Fig. 57. Projection of the LaAgGe unit cell and coordination polyhedra of the atoms: (a) La, (b,c) Ag and Ge.

3.19.10. *KHg<sub>2</sub> structure type*SG  $Imma$ ,  $Z=4$ ,  $a=0.4366$ ,  $b=0.6956$ ,  $c=0.7596$  for HoPdGe (Sologub and Salamakha 1999)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Ho	4(e)	0	1/4	0.5402	100
X	8(h)	0	0.0473	0.1651	100

 $X=0.5Pd+0.5Ge$ 

Isotypic compounds:

RPdGe: R = Y, La–Sm, Gd–Tm

RPtGe: R = Ce–Nd

The coordination polyhedra for holmium atoms have 18 apexes (fig. 58a). The statistical mixture X ( $X = 0.5\text{Pd} + 0.5\text{Ge}$ ) occupies the centre of trigonal prism with four additional atoms (fig. 58b).

Fig. 58. Projection of the HoPdGe unit cell and coordination polyhedra of the atoms: (a) Ho, (b) X.

Fig. 59. Projection of the HoRuGe unit cell and coordination polyhedra of the atoms: (a) Ho, (b) Ru, (c) Ge.

### 3.19.11. *TiNiSi* structure type

SG  $Pnma$ ,  $Z = 4$ ,  $a = 0.6980$ ,  $b = 0.4351$ ,  $c = 0.7281$  for HoRuGe (Sologub et al. 1993)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Ho	4(c)	0.00850	1/4	0.69089	100
Ru	4(c)	0.1562	1/4	0.0638	100
Ge	4(c)	0.2042	1/4	0.3771	100

Isotypic compounds:

RCoGe: R = Sc, Y, Sm, Gd–Lu

RNiGe: R = Sc, Y, Ce–Sm, Gd–Lu

RRuGe: R = Gd–Tm

RRhGe: R = Sc, Y, Ce–Sm, Gd–Tm

RIrGe: R = Sc, Y, Ce–Sm, Gd–Tm

RPtGe: R = Sc, Y, Sm, Gd–Tm

The polyhedra with 18 apexes are typical for the holmium atoms (fig. 59a). The polyhedra for ruthenium atoms are deformed cubo-octahedra (fig. 59b). The germanium coordination polyhedra are trigonal prisms with four additional atoms (fig. 59c).

Fig. 60. Projection of the HoAgGe unit cell and coordination polyhedra of the atoms: (a) Ho, (b) Ag, (c, d) Ge.

### 3.19.12. *ZrNiAl* structure type

SG  $P\bar{6}2m$ ,  $Z=3$ ,  $a=0.7084$ ,  $c=0.4179$  for HoAgGe (Sologub and Protsyk 1991)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Ho	3(f)	0.5883	0	0	100
Ag	3(g)	0.255	0	1/2	100
Ge1	2(d)	1/3	2/3	1/2	100
Ge2	1(a)	0	0	0	100

Isotypic compounds:

RLiGe: R = Y, Pr–Sm, Gd–Lu

RAgGe: R = Sc, Y, Sm, Gd–Lu

RAg<sub>1+x</sub>Ge<sub>1-x</sub>: R = Pr, Nd

ScMGe: M = Cu, Ru, Rh, Pd, Os

For holmium atoms, polyhedra with 17 apexes are typical (fig. 60a). The silver atom polyhedra are distorted cubo-octahedra (fig. 60b). The trigonal prisms with three additional atoms are the polyhedra for germanium atoms (fig. 60c, d).

### 3.19.13. *LaPtSi* structure type

SG  $I4_1md$ ,  $Z=4$ ,  $a=0.42663$ ,  $c=1.4970$  for LaPtGe (Hovestreydt et al. 1982)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
La	4(a)	0	0	0.581	100
Pt	4(a)	0	0	0.1660	100
Ge	4(a)	0	0	0.000	100

Fig. 61. Projection of the LaPtGe unit cell and coordination polyhedra of the atoms: (a) La, (b,c) Pt and Ge.

#### Isotypic compound: LaIrGe

The coordination polyhedra of lanthanum have 20 apexes (fig. 61a). The trigonal prisms with three additional atoms are the polyhedra for platinum and germanium atoms (fig. 61b,c).

#### 3.19.14. *ZrOS (or LaIrSi) structure type*

SG  $P2_13$ ,  $Z=4$ ,  $a=0.65463$  for EuPtGe (Pöttgen et al. 1996)

Atom	Wyckoff notation	$x/a$	$y/b$	$z/c$	G (%)
Eu	4(a)	0.13207	0.13207	0.13207	100

## 4. Structure types of quaternary rare-earth germanides

### 4.1. $R(M, M'Ge)_4$ compounds

Investigation of the quaternary alloys has been carried out mainly between two isotypic compounds, gradually substituting one of the components in the initial compounds. Thus, as typical for the ternary phases, the  $CeGa_2Al_2$  structure type also occurs in the quaternary compounds  $Y_xR_{1-x}Mn_2Ge_2$  ( $R=La, Lu$ ) (Venturini 1996),  $Sm_xR_{1-x}Mn_2Ge_2$  ( $R=Y, Gd$ )

(Duraj et al. 1989),  $\text{Nd}_x\text{U}_{1-x}\text{M}_2\text{Ge}_2$  ( $\text{M}=\text{Mn}, \text{Co}, \text{Ni}, \text{Cu}$ ) (Sologub and Salamakha 1998),  $\text{LaMn}_{2-x}\text{M}_x\text{Ge}_2$  ( $\text{M}=\text{Fe}, \text{Cu}$ ) (Venturini and Malaman 1996),  $\text{LaRu}_x\text{Rh}_{2-x}\text{Ge}_2$  (Venturini et al. 1989b). The same authors show, that when the  $\text{LaM}_2\text{Ge}_2$  ternary compounds crystallize with the structure types of  $\text{CeGa}_2\text{Al}_2$  (for  $\text{M}=\text{Ru}, \text{Rh}, \text{Pd}$ ) and of  $\text{CaBe}_2\text{Ge}_2$  (for  $\text{M}=\text{Ir}$ ), solid solutions originating from the ternary compounds are found to exist.

The formation of compounds with four individual components with the  $\text{CaBe}_2\text{Ge}_2$  structure becomes possible when the initial ternary compounds crystallize with the  $\text{CeGa}_2\text{Al}_2$  (SG I4/mmm) and  $\text{LaPt}_2\text{Ge}_2$  (SG  $\text{P}2_1$ ) types of structure:  $\text{LaPt}_{1.2}\text{Ru}_{0.8}\text{Ge}_2$ ,  $\text{LaPt}_{1.1}\text{Rh}_{0.9}\text{Ge}_2$ , and  $\text{LaPt}_{0.7-1.4}\text{Pd}_{1.3-0.6}\text{Ge}_2$ . The compound  $\text{LaPt}_{1.42}\text{Pd}_{0.58}\text{Ge}_2$ , however, forms a unique structure type which is a superstructure to the  $\text{CaBe}_2\text{Ge}_2$  type. Atomic coordinates for this type are presented below.

#### 4.1.1. $\text{LaPt}_{1.42}\text{Pd}_{0.58}\text{Ge}_2$ structure type

## 5. Discussion

In many cases, ternary germanides of rare-earth metals crystallize with the structure types characteristic for the compounds with silicon which have been discussed extensively in the reviews of Gladyshevsky and Bodak (1982) and Parthé and Chabot (1984). The analysis of many structure types of germanium containing compounds was presented by Gladyshevsky et al. (1990). Our discussion will not be concerned with those types that have been considered in these three surveys.

### 5.1. Classification of the ternary structure types of the germanides

The rare-earth atoms in the above described compounds are generally the largest atoms in the unit cells. Therefore their structure types can be categorized as definite classes in the classification scheme of Kripyakevich (1977), by the coordination number and coordination polyhedra of the atoms of other components with the smaller radii.

Among the R–M–Ge compounds, the most important three classes of structure types are: (1) class 5 with a coordination number equal to 12, and the icosahedron coordination polyhedron; (2) class 9 with coordination numbers of 8–10 and a tetragonal antiprism coordination polyhedron; (3) class 10 with coordination numbers of  $6+n$  ( $n=1, 2, 3$  or 5) and a trigonal prism coordination polyhedron and its derivatives.

#### 5.1.1. Structure types with icosahedral coordination of the smallest atoms

The compound  $\text{Nd}_2\text{Cr}_9\text{Ge}_8$  is the first representative of a novel structure type. The coordination polyhedra for the smallest atoms (Cr and Ge) have the form of an icosahedron and its derivatives. The  $\text{Nd}_2\text{Cr}_9\text{Ge}_8$  structure can be considered as a linear stacking of the  $\text{CaCu}_5$  segments and hypothetical  $\text{RX}_{12}$  slabs (fig. 90).

The  $\text{ErCo}_3\text{Ge}_2$  (or  $\text{Er}_{6-x}\text{Co}_6\text{Ge}_4$ ) structure is a defected derivative from  $\text{CaCu}_5$  and differs from the present structure by a slight shift of the  $x$  coordinate of Co atoms from the site 3(g),  $\frac{1}{2} 0 \frac{1}{2}$ . As result, the symmetry is changed, and the  $c$  lattice parameter is doubled.

A part of the same atomic positions from the  $\text{CaCu}_5$  structure are retained in  $\text{YCo}_6\text{Ge}_6$ , which is formed by the substitution of R atoms by pairs of M atoms. The  $\text{RM}_6\text{Ge}_6$  compounds crystallize with different structure types, and in most cases polymorphism is observed in these compounds. All of these structure types are related with the  $\text{YCo}_6\text{Ge}_6$  type. The lattice parameters for the  $\text{RM}_6\text{Ge}_6$  structures expressed as the lattice parameters of  $\text{YCo}_6\text{Ge}_6$  ( $a_1, c_1$ ) are presented in table 1.

Fig. 90. Structure type  $\text{Nd}_2\text{Cr}_9\text{Ge}_8$  as a linear hybrid of  $\text{CaCu}_5$  and hypothetical  $\text{RX}_{12}$  structure.

Table 1  
Structure types of germanides, related with  $\text{YCo}_6\text{Ge}_6$  type

Structure type	Space group	Representatives	Lattice parameters		
			$a$	$b$	$c$
$\text{YCo}_6\text{Ge}_6$	P6/mmm	$\text{RCO}_6\text{Ge}_6$ (R = Gd–Lu)	$a_1$	$a_1$	$c_1$
$\text{MgFe}_6\text{Ge}_6$	P6/mmm	$\text{RCr}_6\text{Ge}_6$ (R = Y, Tb–Er)	$a_1$	$a_1$	$2c_1$

### 5.1.2. Structure types with tetragonal antiprismatic coordination of the smallest atoms

An example of the tetragonal antiprism polyhedron ( $\text{R}_4\text{M}_4$ ) is a fragment typical for the  $\text{BaAl}_4$  structure. The structure types with tetragonal antiprismatic coordination generally occur at a rare-earth concentration of  $\text{R} \approx 20\%$ . The structures which are built from  $\text{BaAl}_4$  fragments are presented in table 2.

Table 2

### 5.1.3. Structure types with trigonal prismatic coordination of the smallest atoms

Among ternary germanides of rare earths, the most widespread are the structure types which belong to the trigonal prismatic category. In these structures, the trigonal prisms can completely occupy the space without gaps to form columns, walls and stacks, or to connect the peaks (edges). This fragment which is formed by the six large (R) atoms at the corners, and the small seventh one (M or X) inside it gives the  $\text{AlB}_2$  type. The

Table 3  
Distorted, substituted and vacancy derivatives of  $AlB_2$  in ternary rare-earth germanides

Structure type	Space group	Representatives
$AlB_2$	$P6/mmm$	$RCuGe$ , $R = La-Sm$
$CaIn_2$	$P6_3/mmc$	$RCuGe$ , $R = Gd-Yb$
$KHg_2$	$Imma$	$R(Pd, Ge)_2$ , $R = Gd-Yb$ ; $YbAuGe$
$ZrBeSi$	$P6_3/mmc$	$EuZnGe$
$LiGaGe$	$P6_3/mc$	$RAgGe$ , $R = La-Pr$ ; $RAuGe$ , $R = Sc, Y, La-Sm, Gd-Yb$
$DyAlGe$	$Cmc2_1$	$DyAlGe$
$YAlGe$	$Cmcm$	$RAIge$ , $R = Y, Gd-Tm$
$TiNiSi$	$Pnma$	$RCoGe$ , $R = Sc, Y, Sm, Gd-Yb$ ; $RNi(Pt)Ge$ , $R = Sc, Y, Ce-Sm, Gd-Yb$

$CaCuGe$	$Pna2_1$	$EuCuGe$
$\alpha$ - $YbAuGe$	$Pnma$	$YbAuGe$
$\beta$ - $YbAuGe$	$Pnma$	$YbAuGe$
$EuAuGe$	$Imm2$	$EuAuGe$ , $YbAu_{1.24}Ge_{0.76}$

structure types related with the farther structure type  $AlB_2$  by various deformations are presented in table 3.

The new structural types  $YAlGe$ , and  $\alpha$ - $YbAuGe$  and  $\beta$ - $YbAuGe$  are the centrosymmetric variants of the earlier observed  $DyAlGe$  type and  $CaCuGe$  type, respectively.  $EuAuGe$  is a superstructure to the  $KHg_2$  type.

Mutual rotation of plane segments by  $90^\circ$  in the  $AlB_2$  structure leads to the formation of  $\alpha$ - $ThSi_2$ ,  $\alpha$ - $GdSi_2$ ,  $LaPtSi$  and  $CeGe_{0.66}Si_{0.92}$  types.

### 5.2. Formation of superstructures

Structure types may have the same positions of atoms, but differ by the number of components substituting at these positions. Simultaneously, the symmetry and outline of the unit cell may be changed. An ordered substitution of the atom positions by different atoms leads to the formation of superstructures. An increase of the number of components in a compound enhances the number of possible variants of their distribution over the atom positions of the parent structure.

Table 4 demonstrates the superstructures which are formed as a result of an ordered substitution of the smallest atoms in the initial binary structure type by the other small atoms.

The structure type  $Y_3NiAl_3Ge_2$  is an example of a quaternary substitution variant of a binary structure type:  $Fe_2P \rightarrow ZrNiAl \rightarrow Y_3NiAl_3Ge_2$  (SG  $P\bar{6}2m$ ). The partly ordered occupation of the atomic positions of Be in the  $CaBe_2Ge_2$  structure by the transition metal atoms leads to the formation of the  $LaPt_{1.42}Pd_{0.58}Ge_2$  superstructure.

Table 4  
Formation of superstructures by ordered substitution of smaller atoms

Structure type	Space group	Structure type	Space group
Yb <sub>3</sub> Sb <sub>3</sub>	Pnma	Ce <sub>3</sub> RuGe <sub>2</sub>	Pnma
Nd <sub>3</sub> Ir <sub>3</sub>	P4/ncc	Ce <sub>3</sub> NiGe <sub>2</sub>	P4/ncc
EuMg <sub>5</sub>	P6 <sub>3</sub> /mmc	Se <sub>3</sub> Ni <sub>11</sub> Si <sub>4</sub>	P6 <sub>3</sub> /mmc

CaIn <sub>2</sub>	P6 <sub>3</sub> /mmc	LiGaGe	P6 <sub>3</sub> mc
Fe <sub>2</sub> P	P6̄2m	ZrNiAl	P6̄2m
Eu <sub>3</sub> Ga <sub>8</sub>	Immm	U <sub>3</sub> Ni <sub>4</sub> Si <sub>4</sub>	Immm
Ni <sub>2</sub> In	P6 <sub>3</sub> /mmc	ZrBeSi	P6 <sub>3</sub> /mmc
PbCl <sub>2</sub>	Pnma	TiNiSi	Pnma
SrSi <sub>2</sub>	P2 <sub>1</sub> 3	ZrOS	P2 <sub>1</sub> 3

The LaTmIrGe<sub>2</sub> structure is a superstructure of YIrGe<sub>2</sub> and is formed as a consequence of an ordered occupation of large atoms in the initial structure by rare-earth atoms with different sizes.

The occupation of the atomic positions of Cr in the Cr<sub>23</sub>C<sub>6</sub> structure by the large Ce atoms and the small Pd atoms gives the new Ce<sub>3</sub>Pd<sub>20</sub>Ge<sub>6</sub> structure type, i.e. a superstructure of the Cr<sub>23</sub>C<sub>6</sub> type.

A new structure type EuAuGe was derived from the binary KHg<sub>2</sub> structure by an ordered arrangement of the Eu(1) and Eu(2) atoms substituting on the K positions, and the Au and Ge atoms on the Hg positions of KHg<sub>2</sub>. Thus, EuAuGe is a superstructure of the binary intermetallic KHg<sub>2</sub>.

### 5.2.1. Formation of superstructures of the binary rare-earth germanides

The crystal structure of Ho<sub>26</sub>Pd<sub>4</sub>(Pd,Ge)<sub>19-x</sub> represents a substitutional variant of the Er<sub>26</sub>Ge<sub>23-x</sub> structure type. The difference between the two structures lies only in the replacement of germanium atoms by palladium atoms in positions 2(c) and 8(j) and the presence of a statistical distribution of Ce and Pd atoms in positions 2(c) and 8(i). Other isotypical ternary phases are not known. Only the compound Ce<sub>26</sub>Li<sub>5</sub>Ge<sub>23-y</sub>, where the Li atoms occupy the 2(b) and 8(i) positions which are vacant in the previous phases, has a similar structure (table 5).

The formation of superstructures from the Sm<sub>5</sub>Ge<sub>4</sub> type originates from an ordered occupation of the Sm atomic positions by other atoms (table 6). The symmetry of the structures remains unchanged.

Table 5

The compound  $\text{Gd}_5\text{Si}_2\text{Ge}_2$  occurs between two isotypic binary compounds,  $\text{Gd}_5\text{Si}_4$  and  $\text{Gd}_5\text{Ge}_4$  (structure type  $\text{Sm}_5\text{Ge}_4$ ). An internal deformation in the structure leads to the exterior one. The initial orthorhombic structure transforms to a monoclinic structure.

In contrast to the previously described examples, the formation of three types of superstructures of the  $\text{Ho}_{11}\text{Ge}_{10}$  type is possible (table 7):

- (i) an ordered substitution of the site originally occupied by the large atom 16(n) –  $\text{Sc}_{11-x}\text{Yb}_x\text{Ge}_{10}$ ;
- (ii) an ordered substitution of the site originally occupied by the small atom 8(h) –  $\text{Sc}_{11}\text{Al}_2\text{Ge}_8$ .
- (iii) an  $\text{Sc}_7\text{Mn}_{4-x}\text{Ge}_{10-x}$  structure: the Mn atom occupies the 16(n) position, and the statistical mixture (Mn, Ge) fills the 8(h) position.

Table 7

### 5.3. Analysis of some new structure types

The atoms in the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$  structure are located in two planes with  $x = \frac{1}{4}$  and  $x = \frac{3}{4}$ . The metal atoms form trigonal prisms with their axes parallel to one another. The prisms centered by germanium atoms form two types of blocks:  $\text{HoIr}_6\text{Ge}_3$  and  $\text{Ho}_3\text{Ir}_{10}\text{Ge}_6$  which are mutually connected through empty trigonal prisms formed by iridium atoms. The blocks are shifted with respect to each other by a half translation along the shortest ( $a$ ) axis (fig. 91). A survey of the literature of known structure types revealed that these blocks are typical for compounds such as  $\text{YNi}_5\text{Si}_3$  (fig. 91, a) and  $\text{Y}_6\text{Ni}_{20}\text{P}_{13}$  (fig. 91, b).

The unit cell dimensions of the  $\text{Ce}_2\text{Pt}_7\text{Ge}_4$  structure correspond to the lattice parameters of the previous one. The atoms of cerium and platinum produce trigonal prisms in which the germanium atoms are located. Three trigonal prisms combine with each other owing to a common edge to give a typical "star". The fourth prism has a common edge with one of these prisms. This fragment corresponds to the composition  $\text{Ce}_2\text{Pt}_7\text{Ge}_4$ . The packing arrangement of the prisms in the  $\text{Ce}_2\text{Pt}_7\text{Ge}_4$  structure are shown in fig. 92. The distance between two similarly oriented "star" fragments in terms of the lattice parameter  $a$  is  $1/2a$ . The crystal structure of  $\text{Ce}_2\text{Pt}_7\text{Ge}_4$  (I) is similar to that of the compound  $\text{Nd}_2\text{Ni}_7\text{P}_4$  (II) (space group  $\text{Pmn}2_1$ ) ( $a_{\text{I}} \approx 2b_{\text{II}}$ ,  $b_{\text{I}} \approx a_{\text{II}}$ ,  $c_{\text{I}} \approx c_{\text{II}}$ ) in which the packing of the same "stars" is observed.

In the ternary cross section of the Ce–Pt–Ge system the compound  $\text{Ce}_3\text{Pt}_4\text{Ge}_6$  is located between  $\text{CePt}_2\text{Ge}_2$  and  $\text{CePtGe}_2$ . Analysis of the crystal structures shows  $\text{Ce}_3\text{Pt}_4\text{Ge}_6$  to be a combination of the two structures. The relationship between the  $\text{CePt}_2\text{Ge}_2$ ,  $\text{Ce}_3\text{Pt}_4\text{Ge}_6$  and  $\text{CePtGe}_2$  structures is shown in fig. 93. The marked fragment in  $\text{CePtGe}_2$  (structural type  $\text{NdIrGe}_2$ ) has the composition  $\text{Ce}_2\text{Pt}_2\text{Ge}_4$ . The composition  $2\text{Ce}_3\text{Pt}_4\text{Ge}_6$  is the result of the following fragment packing:  $\frac{1}{2}\text{Ce}_2\text{Pt}_2\text{Ge}_4 + \text{CePt}_2\text{Ge}_2 + \text{Ce}_2\text{Pt}_2\text{Ge}_4 + \text{CePt}_2\text{Ge}_2 + \frac{1}{2}\text{Ce}_2\text{Pt}_2\text{Ge}_4$ .

Fig. 92. The interrelation between  $\text{Ce}_2\text{Pt}_7\text{Ge}_4$  and  $\text{Nd}_2\text{Ni}_7\text{P}_4$  structures.

Fig. 91. Blocks of atoms, typical for the structures related to the  $\text{Ho}_4\text{Ir}_{13}\text{Ge}_9$  type: (a)  $\text{YNi}_5\text{Si}_3$  and (b)  $\text{Y}_6\text{Ni}_{20}\text{P}_{13}$ .

The structural type  $\text{Y}_3\text{Pt}_4\text{Ge}_6$  is monoclinically deformed  $\text{Ce}_3\text{Pt}_4\text{Ge}_6$  with  $a \approx 2a$ ,  $b \approx b$  and  $c \approx \frac{1}{2}c$ . The structure of  $\text{Y}_3\text{Pt}_4\text{Ge}_6$  is a stacking variant of the monoclinic structures  $\text{LaPt}_2\text{Ge}_2$  and  $\text{NdIrGe}_2$ .

The  $\text{Nd}_4\text{Rh}_4\text{Ge}_3$  structure type can be described as a stacking of fragments typical for the  $\text{YPd}_2\text{Si}$  and  $\text{La}_3\text{Ni}_2\text{Ga}_2$  structures (fig. 94). In turn, the  $\text{La}_3\text{Ni}_2\text{Ga}_2$  structure consists of  $\text{YAlGe}$  and  $\text{CrB}$  fragments.

The structure types  $\text{Ce}_2(\text{Ga}_{0.9}\text{Ge}_{0.1})_7$  and  $\text{La}_2\text{Al}_{1+x}\text{Ge}_{6-x}$  are the vacancy variant of the orthorhombic  $\text{SmNiGe}_3$  and can be considered as an intergrowth of  $\text{AlB}_2$ -, deformed  $\text{Po}$ - and partially vacant  $\text{BaAl}_4$ -type slabs.

The  $\text{Yb}_7\text{Al}_5\text{Ge}_8$  structure type can be considered as an intergrowth of  $\text{TiNiSi}$ -,  $\text{AlB}_2$ - and  $\text{CsCl}$ -type columns.

The new structure types  $\text{CeRh}_{1-x}\text{Ge}_{2+x}$  and  $\text{Ce}_2\text{Cu}_3\text{Ge}_3$  are formed as a result of an internal deformation of the  $\text{CeNiSi}_2$  structure; the unit cell dimensions, however, remain unchanged. The  $\text{TmLi}_{1-x}\text{Ge}_2$  structure is a monoclinically deformed derivative of the  $\text{CeNiSi}_2$  structure and it can be described as a result of an inclusion of  $\text{Li}$  atoms into the empty tetragonal prisms which are typical for the  $\text{CaSb}_2$  structure.

The  $\text{TmLi}_{1-x}\text{Ge}_2$ ,  $\text{CeRh}_{1-x}\text{Ge}_{2+x}$  and  $\text{Ce}_2\text{Cu}_3\text{Ge}_3$  structures together with  $\text{CeNiSi}_2$ ,  $\text{TbFeSi}_2$  and  $\text{U}_3\text{Ni}_4\text{Si}_4$  are the members of the homological series of compounds with the common formulae  $\text{R}_{m+0.5n}\text{M}_{2m}\text{X}_{2n}$  where  $m$  is the number of  $\text{AlB}_2$  fragments and  $n$  is the number of  $\text{BaAl}_4$  fragments. For  $\text{TmLi}_{1-x}\text{Ge}_2$ ,  $m=1$  and  $n=2$ ; for the  $\text{CeRh}_{1-x}\text{Ge}_{2+x}$ ,  $\text{Ce}_2\text{Cu}_3\text{Ge}_3$ ,  $\text{CeNiSi}_2$  and  $\text{TbFeSi}_2$  structures  $m=2$  and  $n=4$ ; and for  $\text{U}_3\text{Ni}_4\text{Si}_4$ ,  $m=n=4$ .

Fig. 93. The interrelation between  $\text{CePt}_2\text{Ge}_2$ ,  $\text{Ce}_3\text{Pt}_4\text{Ge}_6$  and  $\text{CePtGe}_2$  structures.

Fig. 94. The  $\text{Nd}_4\text{Rh}_4\text{Ge}_3$  as a stacking of (I)  $\text{YPd}_2\text{Si}$  and (II)  $\text{La}_3\text{Ni}_2\text{Ga}_2$  fragments.

## List of symbols

<i>A</i>	Coefficient of resistivity ( $\rho_{\text{mag}}=AT^2$ )	bcc	Body centered cubic
<i>A<sub>4</sub>, A<sub>6</sub></i>	Crystal field parameters	<i>C</i>	Curie constant
<i>a, b, c</i>	Lattice parameters	<i>c</i>	Total heat capacity
<i>B</i>	Magnetic induction	<i>CF</i>	Crystal field

CN	Coordination number	$W_{e,0}$	Residual thermal resistivity
CP	Coordination polyhedron	$W_{e,ph}$	Thermal resistivity due to phonon scattering
$c_m$	Magnetic heat capacity		
$\Delta c$	Difference in the heat capacity at $T_S$	$W_{e,sf}$	Thermal resistivity due to spin fluctuation scattering
<i>cub</i>	Cubic symmetry		
dhcp	Double hexagonal close packed	$x, W$	Crystal field parameters of cubic systems
DOS	Density of states		
$E$	Eutectic transition	$X, X'$	p-element
$Ed$	Eutectoid transition	$\alpha$	Thermal expansion coefficient
fcc	Face centered cubic	$\alpha, \beta, \gamma$	Lattice parameters
hcp	Hexagonal close packed	$\alpha_n, \beta_n, \gamma_n$	Specific heat coefficients in the normal state
<i>hex</i>	Hexagonal symmetry		
HT	High temperature	$\alpha_s, \beta_s, \gamma_s$	Specific heat coefficients in superconducting state
$iL$	Immiscibility gap in liquid		
$L$	Congruently melting compound; liquid	$\beta$	Lattice specific heat coefficient
LT	Low temperature	$\chi$	Magnetic susceptibility
$M$	Magnetization	$\chi_0$	Temperature independent magnetic susceptibility
$M, M'$	Metallic element (s-, d-, f-element)		
$Mt$	Metatectic transition	$\gamma$	Electronic specific heat coefficient
$N(\epsilon_F)$	Density of states at the Fermi level	$\epsilon_F$	Fermi energy
<i>orthorh</i>	Orthorhombic symmetry	$\lambda$	Total thermal conductivity
$P$	Peritectic transition	$\lambda_l$	Lattice thermal conductivity
$Pd$	Peritectoid transition	$\lambda_e$	Electronic thermal conductivity
$p_s$	Saturation moment	$\mu_B$	Bohr magneton
$S$	Polymorphic transition	$\mu_{Fe}$	Bohr magneton per Fe atom
$S, S_{tot}$	Total thermopower	$\mu_{eff}$	Effective magnetic moment
$S_{diff}$	Diffusion thermopower	$\rho, \rho_{ges}$	Total electrical resistivity
$S_{drag}$	Thermopower due to drag effects	$\rho_0$	Residual electrical resistivity
SG	Space group	$\rho_{sf}$	Electrical resistivity due to spin fluctuation scattering
ST	Structure type		
s,p,d,f	Band index	$\rho_{mag}$	Electrical resistivity due to magnetic scattering
<i>tetr</i>	Tetragonal symmetry	$\rho_{ph}$	Electrical resistivity due to phonon scattering
$T_{sf}$	Spin fluctuation temperature		
$T_C$	Curie temperature	$\Delta\rho/\rho$	Magnetoresistance
$T_N$	Néel temperature	$\sim$	Precedes the composition formula of a compound to indicate that the composition is given tentatively
$T_S$	Superconducting transition temperature		
$W$	Total thermal resistivity		

## 1. Introduction

The last comprehensive treatment of scandium as an element and of its alloys and compounds was given in the book *Scandium. Its occurrence, chemistry, physics, metallurgy, biology and technology* in 1975 (Gschneidner 1975). Meanwhile numerous

structural investigations have been published in the literature mainly concerning structural properties. It seems that the time is ready to summarise the new results with the aim to give an overview over the last most significant and relevant results. Since one of us (B.K.) has been working for more than twenty years in the field of structural and chemical investigations of scandium-based alloys and compounds, it is obvious that problems such as phase stability and the phase diagrams represent the main part of the chapter. Many investigations of ternary scandium-based phase diagrams have been investigated and published since 1975. However, there are also numerous new investigations of binary compounds and their phase diagrams are now known, and these are included in this chapter. The aim is to give an overview of the newly published data up to the beginning of 1997. In sections 2 and 3 the binary and ternary scandium containing systems are treated, whereas sect. 4 is dedicated to multicomponent systems.

At the beginning of each section an explanation is given of how the information is subdivided in the subsequent text. Each phase diagram is accompanied by a brief statement about what seems to be necessary for understanding the phase relationships and where the data have been published. Also included are the crystal structure data of binary, ternary and multinary phases as far as they are given in the literature.

Since in some cases the published data are controversial, we have tried to make objective and critical comments to the best of our abilities.

Section 5 presents general trends among the binary and ternary Sc-based intermetallics, since this information may be interesting for the syntheses of new Sc compounds for both basic research as well as for technical applications.

In the last section the physical properties of several selected intermetallic compounds containing scandium are discussed and some of their physical properties are depicted in diagrams. In most of the cases the physical properties of the Sc-containing compounds and those of the isostructural Y, La or Lu compounds are compared.

## 2. Binary systems containing scandium

The phase diagrams of the Sc–E (E=element) binary systems have been investigated in the entire or partial concentration region for majority of elements. These data are presented in summarised form in table 1. The data have been obtained primarily from the original papers, supplemented by data from the 2nd edition of *Binary Alloy Phase Diagrams* by Massalski (1990) and from the 2nd edition of *Pearson's Handbook of Crystallographic Data for Intermetallic Phases* by Villars and Calvert (1991).

There are no data for about 24 Sc–E binary systems out of 89 possible. Among them there are 10 systems with the transuranium elements with atomic numbers higher than 95. The phase diagrams of 54 Sc–E binary systems have been investigated for the entire or partial concentration region up to the beginning of 1997. The figures of the phase diagrams of binary systems presented and discussed by Gschneidner (1975) are not shown in this section if no additional controversial literature data appeared in the meantime. In these cases a brief summary and references are given. 23 binary phase diagrams have been

<sup>a</sup> The squares indicate the concentration range in which the phase diagram of the Sc-E binary system was investigated: black square, 75–100%; grey square, 25–75%; open square, less than 25%; no square, not investigated.

The number of binary compounds found is listed next to the square.

The character of the mutual solubility of Sc and E is indicated as follows:

*iL*, miscibility gap in the liquid state;

*E*, mutual solubility in the solid state <1 at.% (simple eutectic, no binary compound occurs);

→, solubility of Sc in solid E >1 at.%;

←, solubility of E in solid Sc >1 at.%;

∞, at least one continuous solid solution of Sc and E occurs.

published after Gschneidner's review article in 1975. These diagrams will be discussed in more detail. All controversial data about the systems will be analysed and discussed. In some cases necessary corrections are made and the revised phase diagrams are presented, whereas in other cases diverging results in the literature are only mentioned. The data in the section are arranged according to the stretched form of the periodic table of elements. Within one group of elements the systems are given according to increasing atomic number of the elements. The data about all scandium binary intermetallics including

their composition, melting temperature (in °C) and crystallographic data (structure type (ST) or symmetry and lattice parameters) are presented. The reference source of the crystallographic data is presented first followed by the references in which these data appeared. The reference source with data of the melting temperature of compound is printed in italics. The following abbreviations are used for compounds' formation and decomposition:

- L*, congruently melting compound;
- P*, peritectically melting compound;
- Pd*, compound is formed according to peritectoid reaction;
- S*, polymorphic transition;
- Ed*, compound decomposes according to eutectoid reaction;
- Mt*, metatectic transition.

### 2.1. *Sc-M (M = 1A element) systems*

There are no data about the interaction of scandium with the alkaline metals. Taking into consideration the large differences in the melting temperatures of Sc and 1A elements the occurrence of immiscibility gaps in liquid and solid binary alloys are possible as they occur in the Sc-E (E = alkaline-earth element) alloys (see sect. 2.2). The absence of binary compounds in these systems is very likely.

### 2.2. *Sc-M (M = 2A element) systems*

Occurrence of three scandium-beryllium intermetallic compounds and their crystal structures are the only data existing about the Sc-Be binary system. Their characteristics are presented in table 2. Gschneidner and Calderwood (1987) reviewed all available papers on scandium-beryllium binary alloys.

Beaudry and Daane (1969) established the Sc-Mg phase diagram in the range of 0–60 at.% Sc.  $\beta$ Sc dissolves up to 80 at.% Mg and magnesium dissolves up to 15 at.% Sc. The latter data was refined by Sviderskaya and Nikitina (1972), who established the

Fig. 1. The Sc-Ca phase diagram.

Fig. 2. The Sc-Sr phase diagram.

temperature dependence of the solubility of Sc in Mg. One binary compound ScMg with a broad homogeneity range, isotypic with CsCl, occurs in the system (table 2). Reviews of the papers on Sc-Mg alloys have been given by Gschneidner (1975) and by Nayeb-Hashemi and Clark (1986). The latter authors presented the assessed phase diagram of the system with only few small corrections of the earlier data of Beaudry and Daane (1969). New data concerning the phase diagram are not known.

Dzuraev and Altynbaev (1986) determined the solubility of Sc in  $\beta\text{Ca}$ ,  $\beta\text{Sr}$  and Ca and Sr in  $\beta\text{Sc}$  and  $\alpha\text{Sc}$  as well as the temperatures of the monotectic and eutectic reactions

Fig. 3. The Sc-Ba phase diagram.

in the Sc-Ca and Sc-Sr systems. The Sc-Ca and Sc-Sr phase diagrams constructed on the base of these data are presented in figs. 1 and 2, respectively.

The phase diagram of Sc-Ba system has been reported by Altynbaev et al. (1988). The allotropic transition  $\beta\text{Sc} \leftrightarrow \alpha\text{Sc}$ , which was not shown by these authors, has been added to the phase diagram presented in fig. 3. The melting temperature for Sc has been corrected for the now accepted value.

The interaction of scandium with the earth alkaline elements is similar. An immiscibility gap occurs in the liquid alloys and no binary compound exists in any of these systems.

### 2.3. Sc-M ( $M = \text{RE}$ ) systems

The majority of the data concerning binary Sc-RE systems have been obtained between 1960 and 1970. Since that time practically no new information has been published on the Sc-RE phase diagrams.

The Sc-Y phase diagram was investigated by Beaudry and Daane (1963). The HT and LT modifications of scandium and yttrium are completely miscible in each other. The list of references concerning this system and the phase diagram with the corrected temperatures of phase transitions can be found in the reviews of Gschneidner (1975) and Gschneidner and Calderwood (1983e, 1986a).

Naumkin et al. (1970) investigated the Sc-La phase diagram.  $\gamma\text{La}$  and  $\beta\text{Sc}$  form continuous series of solid solutions, while  $\beta\text{La}$ ,  $\alpha\text{La}$  and  $\alpha\text{Sc}$  dissolve from 12 to 16 at.% of the second component. The phase diagram and the reference list are given by Gschneidner (1975) and Gschneidner and Calderwood (1982a, 1986a).

The Sc–Ce phase diagram has been determined by Naumkin et al. (1964). Gschneidner (1975) and Gschneidner and Calderwood (1982b, 1986a) corrected only the values of the melting and allotropic transition temperatures of the pure components to conform with the accepted values. The bcc phases of Sc and Ce are completely miscible in each other. The LT modifications of Sc and Ce dissolve about 12 and about 17 at.% of Ce and Sc, respectively.

There are no available data about the phase diagram of the Sc–Pr system. Taking into consideration the data on the Sc–Ce system it is possible to predict a complete mutual miscibility of the components in each other in liquid and in bcc solid phases.  $\alpha$ Sc and  $\alpha$ Pr have different crystal structures (hcp and dhcp respectively), therefore, they probably form limited solid solutions.

Beaudry et al. (1965) investigated the Sc–Nd phase diagram. Pairs of HT and LT phases of these components are completely miscible in each other. The attempts of the authors to find two phase region between the hcp phase of Sc and double hcp phase of Nd failed. This continuous solid solution decomposes beginning at 700°C by forming an immiscibility gap. The phase diagram has been analysed earlier by Gschneidner (1975) and Gschneidner and Calderwood (1982c, 1986a).

There are no data known about investigations of Sc–Pm system.

The only data about interaction between Sc and Sm are those published by Kotur et al. (1991). It was found that at 600°C samarium dissolves about 18 at.% Sc. From a comparison of the phase diagrams of other light RE (La, Ce and Nd) it is possible to predict a complete miscibility of the components in each other in the liquid and solid bcc phases.

Massalski (1990) presented the hypothetical Sc–Eu phase diagram based on thermodynamic calculations of Miedema (1976). They predict the occurrence of a broad immiscibility gap in liquid and solid alloys and the absence of binary compounds in this system.

The phase diagram of Sc–Gd system has been established by Beaudry and Daane (1964). The figure of the phase diagram is also presented in the reviews of Gschneidner (1975) and Gschneidner and Calderwood (1983c, 1986a) who corrected only the values of melting and the bcc  $\leftrightarrow$  hcp transitions temperatures of the components with their new values. One liquid and two solid continuous solutions exist in this system.

The lattice parameters of several Sc–Tb alloys have been measured indicating a complete solubility of  $\alpha$ Tb and  $\alpha$ Sc. These data were reviewed and analysed by Gschneidner (1975) and Gschneidner and Calderwood (1983d, 1986a).

The phase diagram of the Sc–Dy binary system has not been investigated. Kotur et al. (1991) reported about a complete solubility of the components at 600°C. The  $a$  and  $c$  lattice spacing of the hcp solid solution appear to follow Vegard's rule within the experimental error.

Considering the above presented data it is possible to predict the existence of one liquid and two solid rows of continuous solutions in the Sc–Tb and Sc–Dy systems like in the Sc–Gd system. The occurrence of two of these solid solutions ( $\alpha$ Sc,  $\alpha$ Tb) and ( $\alpha$ Sc,  $\alpha$ Dy) has been already confirmed experimentally.

Cavin et al. (1967) reported the lattice spacings of five binary Sc–Ho alloys. Their data were also presented and analysed by Gschneidner (1975) and Gschneidner and Calderwood (1983b, 1986a).  $\beta$ Sc forms a continuous series of solid solutions with holmium.

The Sc–Er phase diagram has been investigated by Naumkin et al. (1964). Gschneidner (1975) and Gschneidner and Calderwood (1983a, 1986a) critically revised and corrected the values of temperatures of all phase transitions presented in the original paper. Er and  $\alpha$ Sc are completely soluble in each other.  $\beta$ Sc dissolves about 24 at.% Er.

There are no known data about the Sc–Tm system in the literature.

Since Ho, Er and Tm have only one solid phase (hcp); it appears that these three binary systems will have similar phase diagrams, i.e. occurrence of one liquid and one solid continuous solutions and a limited solubility in bcc Sc phase. One of such solutions, namely ( $\alpha$ Sc, Ho), has already been determined experimentally.

The hypothetical Sc–Yb phase diagram has been constructed by Massalski (1990) on the basis of thermodynamic calculations of de Boer et al. (1979). Immiscibility gaps in liquid and solid alloys and the absence of binary compounds are predicted for that system. This is in agreement with the data of Kotur (1995) who prepared several binary alloys and observed immiscibility of liquid components and two separate layers in solid alloys.

Kotur and Mokra (1994) reported the complete solubility of scandium and lutetium at 800°C. These are the only available experimental data about the Sc–Lu system. It is possible to predict the complete miscibility of the components in the liquid and a limited solubility of lutetium in  $\beta$ Sc.

#### 2.4. Sc–M (*M* = actinide element) systems

Among the family of the actinide elements data concerning binary systems with scandium only exists for the three elements thorium, uranium and plutonium.

Terekhov and Sinyakova (1990) reported on the Sc–Th phase diagram (fig. 4). Their results are an improvement on the data of Badaeva and Kuznetsova (1969) who were the first to investigate the phase diagram on the basis of thermal analysis of 8 alloys. A continuous series of solid solutions occur between the HT phases of the components.  $\alpha$ Th dissolves up to 66 at.% Sc and  $\alpha$ Sc dissolves up to 20 at.% Th. With decreasing temperature the mutual solubility of the components also decreases. The authors presented a plot of lattice spacing *a* vs. Sc content of the fcc  $\text{Th}_{1-x}\text{Sc}_x$  solid solution at 950°C. As estimated from the plot  $a = 5.095 \text{ \AA}$  for pure  $\alpha$ Th; *a* does not change out to about 7–8 at.% Sc content. In the concentration range  $0.08 < x \leq 0.61$ , *a* follows Vegard's rule with  $a = 4.937 \text{ \AA}$  at  $x = 0.61$ . There is a considerable discrepancy between the values of the melting point of Sc (1530°C) and the  $\alpha$ Sc  $\leftrightarrow$   $\beta$ Sc transition temperature (1415°C) as obtained by Terekhov and Sinyakova (1990) and the now accepted values. For that reason we present in fig. 4 the corrected values for the temperatures of the phase transitions of the pure components.

Figure 5 displays the Sc–U phase diagram established by Terekhov and Sinyakova (1992). No binary compounds and an immiscibility gap in the liquid alloys occur in

Fig. 4. The Sc-Th phase diagram.

Fig. 5. The Sc-U phase diagram.

the system. Okamoto (1993) indicated the necessity of further confirmation of the  $(\beta\text{Sc})/(\beta\text{Sc})+(\alpha\text{Sc})$  boundary since it is too steep and does not follow the van't Hoff relation.

The Sc-Pu phase diagram has been investigated by Kutaitsev et al. (1967), Ellinger et al. (1968, 1972) and Ballagny et al. (1970). These and other papers concerning this system have been analysed in the review of Gschneidner (1975). The diagrams reported by Ellinger et al. (1968, 1972) and Ballagny et al. (1970) are very similar and are the accepted version. HT bcc phases of the components ( $\beta\text{Sc}$ ,  $\epsilon\text{Pu}$ ) are completely miscible in each other. The other phases of Sc ( $\beta$ ) and Pu ( $\delta$ ,  $\delta'$ ,  $\gamma$ ,  $\beta$ ,  $\alpha$ ) form limited solid solutions. One

Table 3  
The intermetallic compound in the Sc–Pu binary system

Compound	Melting temperature (°C)	Structure type or symmetry	Lattice parameters		Reference
			<i>a</i> (Å)	<i>c</i> (Å)	
~Sc <sub>2</sub> Pu <sub>3</sub>	<i>Pd</i> , 753	αLa	3.308– 3.310 <sup>a</sup>	10.709– 10.717	<i>Ellinger et al. (1968)</i>

<sup>a</sup> The first and second values of lattice spacings are for the Sc-rich and Pu-rich side of the homogeneity range, respectively.

binary compound of the approximate composition Sc<sub>2</sub>Pu<sub>3</sub> occurs in the system (table 3). Different authors, however, give different values for the homogeneity limits of Sc<sub>2</sub>Pu<sub>3</sub>, and additional investigations are necessary. Massalski (1990) indicated that the diagram cannot be modelled with a reasonable set of thermodynamic functions and therefore some phase boundaries need further refinement.

### 2.5. Sc–*M* (*M* = 4*A* element) systems

Two variants of the Sc–Ti phase diagram have been reported by Savitskii and Burkhanov (1961) and Beaudry and Daane (1962). Gschneidner (1975) and Murray (1987) analysed them and showed that the Beaudry and Daane one is probably more correct. In these reviews one can find the figure of the phase diagram and the list of references concerning the properties of the Sc–Ti alloys. There are no binary compounds in the system. The bcc HT phases of these components form a continuous series of solid solutions. The hcp LT phases of Sc and Ti dissolve up to 6.9 and 12.8 at.% of the other component, respectively.

Beaudry and Daane (1963) investigated the phase diagram of the Sc–Zr system. The two solid phases of the components are completely miscible in each other. The components also form a continuous liquid solution. These data and the data of other publications on Sc–Zr alloys are presented and reviewed by Gschneidner (1975) and Palenzona and Cirafici (1993).

The Sc–Hf phase diagram is similar to that of Sc–Zr. It was established by Naumkin et al. (1967). Gschneidner (1975) presented the figure of the phase diagram. He corrected only the values of phase transition temperatures of the pure components to the now accepted values. In the review one can find also the list of references concerning the physical properties of Sc–Hf alloys.

### 2.6. Sc–*M* (*M* = 5*A*, 6*A* element) systems

The character of interaction of scandium with 5*A* elements, vanadium, niobium and tantalum and the 6*A* elements, chromium, molybdenum and tungsten is similar. No binary

compounds occur in any of these systems. The components are completely miscible in each other in the liquid state and form simple eutectics.

Savitskii et al. (1970, 1971a) reported on the Sc–V phase diagram. The figure of the phase diagram is also presented in the review of Gschneidner (1975) who corrected the temperatures of phase transitions of pure components to the now accepted values.  $\beta$ Sc and  $\alpha$ Sc dissolve <2 and <0.5 at.% V, respectively. The solubility of Sc in V is <2 at.%. Smith and Lee (1989) noticed an inconsistency of the original phase diagram with van't Hoff's thermodynamic functions. They presented the calculated phase diagram and predicted the occurrence of an immiscibility gap in liquid state in the temperature range from 1593°C to 1459°C and a monotectic reaction occurring at 1459°C. The validity of this theoretical phase diagram needs to be experimentally examined.

The phase diagram of the Sc–Nb system has been reported by Savitskii et al. (1970) and Savitskii and Efimov (1972). The figure of the phase diagram is also presented by Gschneidner (1975). The mutual solubility of the components is as follows: <0.4 at.% Nb in  $\beta$ Sc, <0.3 at.% Nb in  $\alpha$ Sc, and <0.1 at.% Sc in Nb.

Dennison et al. (1966a) established part of the Sc–Ta phase diagram in the high Sc concentration range (0 to 6 at.% Ta). The solubility of Ta in liquid Sc is very low (about 0.2 to 0.5 at.%) but was not determined accurately. According to the data of Taylor et al. (1965) solid Ta dissolves <0.0001 at.% Sc at 1625°C.

Two variants of the Sc–Cr phase diagram have been reported, by Savitskii et al. (1970) and Svechnikov et al. (1972). As was stated by Gschneidner (1975), who preferred the data of Savitskii et al. (1970), the major difference between the two diagrams is that Savitskii et al. found that chromium has insignificant effect on the  $\beta$ Sc  $\leftrightarrow$   $\alpha$ Sc transformation, while Svechnikov et al. (1972) established the transformation to be lowered from 1340 to 990°C by means of an eutectoid reaction. Contrary to Gschneidner (1975), Venkatraman and Neumann (1985) preferred the diagram of Svechnikov et al. and presented the phase diagram based on these data correcting only the phase transition temperatures of the components. Thus, additional experimental investigation of the system is necessary to clarify the situation. Taylor et al. (1965) determined the solubility of Sc in solid Cr to be <0.1 at.%. The value of solubility of Cr in solid Sc is <1 at.% according to the data of Savitskii et al. and <2 at.% according to the data of Svechnikov et al. and needs, perhaps, to be refined too.

Brewer and Lamoreaux (1980) reported on the calculated Sc–Mo phase diagram based on the assumed thermodynamic functions. They predicted an eutectic  $L \leftrightarrow \beta$ Sc + Mo reaction at  $1370 \pm 50^\circ\text{C}$  and an eutectoid  $\beta$ Sc  $\leftrightarrow$   $\alpha$ Sc + Mo reaction at  $\sim 1337^\circ\text{C}$  in this system. The mutual solubility of the components in the solid phases is very low according to their calculation. These data have been partially confirmed by Kotur and Bodak (1988) who investigated several Sc–Mo alloys at 800°C and observed the immiscibility of the components and no binary compounds.

The solubility of tungsten in liquid scandium in the temperature range 1647–2045°C has been determined by Dennison et al. (1966b). They established it to be 2.4–7.9 at.%. The extrapolation of these data towards the melting temperature of Sc, 1541°C, revealed a 1.3 at.% solubility of W. Taylor et al. (1965) determined the solubility of scandium in

solid tungsten as  $<0.004$  at.% at  $1625^{\circ}\text{C}$ . Pandian et al. (1988) used these data to evaluate the hypothetical Sc–W phase diagram. They assumed a temperature of  $1510^{\circ}\text{C}$  for the eutectic reaction  $L \leftrightarrow \beta\text{Sc} + \text{W}$ . The immiscibility of the components in the solid state and absence of binary compounds at  $800^{\circ}\text{C}$  have been confirmed by Kotur et al. (1989a).

### 2.7. Sc–M ( $M = \text{Mn}, \text{Tc}, \text{Re}$ ) systems

The Mn-rich part of the Sc–Mn phase diagram in the range 0–5 at.% Sc has been established by Hellowell (1962). This phase diagram is shown in the review of Gschneidner (1975). The limit of solubility of scandium in  $\beta\text{Mn}$  and  $\delta\text{Mn}$  is about 1 at.%, in  $\gamma\text{Mn}$  it is only 0.4 at.%. Dwight (1961a) reported the existence of one binary compound in the system, namely  $\text{ScMn}_2$  (table 4). His data were confirmed by Kripyakevich et al. (1964). From that time no new data concerning the phase diagram appeared in the literature.

The Sc–Tc phase diagram is still unknown. Darby et al. (1962) synthesised five binary compounds and determined the crystal structure of two of them (table 4).  $\text{ScTc}_7$  was observed in the cast alloy and  $\text{ScTc}_2$  in an alloy annealed at  $700^{\circ}\text{C}$ . Gschneidner (1975) doubted the composition of the  $\text{ScTc}_7$  phase. His reason is that binary compounds isotypic with  $\alpha\text{Mn}$  have in general the 5:24 stoichiometry, i.e. the true composition of the phase must be  $\text{Sc}_5\text{Tc}_{24}$ . This statement needs experimental verification. During the last two decades no new data concerning Sc–Tc phase diagram appeared in the literature.

Savitskii et al. (1966) reported on the Sc–Re phase diagram. It follows from the figure in their paper that the liquidus curve in the phase diagram and the boundaries of some phase fields need additional refinement. Two binary compounds occur in this system (table 4).  $\beta\text{Sc}$  dissolves  $<1$  at.% Re, and the solubility of scandium in solid rhenium does not exceed  $\sim 5$ – $6$  at.%. Gschneidner (1975) presented the data of Savitskii et al., however he corrected in the figure of the phase diagram the temperatures of some phase transitions with the accepted values.

Fig. 6. The Sc-Fe phase diagram.

## 2.8. Sc-M ( $M = Fe, Co, Ni$ ) systems

Naumkin et al. (1969) reported on the Sc-Fe phase diagram. They established the occurrence of two binary compounds  $ScFe_2$  ( $L$ ,  $1600^\circ C$ ) and  $Sc_3Fe$  ( $Pd$ ,  $800^\circ C$ ) but did not investigate their crystal structures. The existence of  $ScFe_2$  is consistent with the earlier data of Dwight (1961a) and Gladyshevsky et al. (1964). Dwight synthesised the  $ScFe_2$  compound and established it to be isotypic with  $MgNi_2$ , SG  $P6_3/mmc$ , with the lattice spacings  $a=4.972$ ,  $c=16.278$  Å. Gladyshevsky et al. obtained an  $ScFe_2$  sample which was isotypic with  $MgZn_2$ , SG  $P6_3/mmc$ , with the lattice spacings  $a=4.92$ ,  $c=7.90$  Å, and in cast alloys with the content of iron less than 50 at.% they observed the occurrence of the cubic  $MgCu_2$ -type structure, SG  $Fd\bar{3}m$ , with the lattice spacing  $a=7.09$  Å.

Taking these data into consideration Bodak et al. (1978) reinvestigated the Sc-Fe phase diagram in the concentration range 0–90 at.% Sc. They confirmed the polymorphism of  $ScFe_2$  (HT phase of  $MgNi_2$  type [given as  $\lambda_3$  in fig. 6] and LT phase of  $MgZn_2$  type [ $\lambda_1$ ]) and discovered a new binary phase  $ScFe_{1.74}$  ( $\lambda_2$ ) with the  $MgCu_2$  type structure. Their lattice spacings are given in table 5. The stoichiometry of the scandium richest binary phase was shown to be about 7:1, not in agreement with the 3:1 stoichiometry found by Naumkin et al. Consequently Kotur et al. (1986a) established the structure and the composition of that phase being  $Sc_{29}Fe_6$  in their single-crystal investigation (table 5).

Kubashewski (1982) presented a revised phase diagram of this system. The only changes which were introduced to the phase diagram of Naumkin et al. were a schematical indication of three polymorphic modifications for  $ScFe_2$ .

The revised phase diagram is shown in fig. 6. The temperatures of the majority of phase transitions are the data of Naumkin et al. since they investigated a larger number of samples, 39 vs. 24 by Bodak et al. The compositions of binary phases, temperatures of phase transitions of the  $ScFe_{1.74}$  and  $ScFe_2$  compounds are the data taken from Bodak

et al. The now accepted temperatures of the phase transitions of the pure components are indicated in the phase diagram shown in fig. 6.

The Sc-Co phase diagram, which is shown in fig. 7 is based primarily on the results reported by Markiv et al. (1978). The authors confirmed the occurrence of the compounds ScCo<sub>2</sub>, ScCo, Sc<sub>2</sub>Co (table 5) and discovered a new one, Sc<sub>3</sub>Co with an orthorhombic unit cell. Chabot and Parthé (1978) established its crystal structure (table 5). There were controversial data about the crystal structure of the Sc<sub>2</sub>Co compound. Gladyshevsky et al. (1964) reported it to be of Ti<sub>2</sub>Ni type, however, these data were not confirmed by Aldred

Fig. 7. The Sc-Co phase diagram in the range 0–90 at.% Sc.

(1962), Kotur et al. (1977a) and Markiv et al. (1978) (table 5). Kotur (1977a) determined the homogeneity range of ScCo<sub>2</sub> phase at 800°C. The lattice spacing increases linearly from  $a = 6.892$  to  $a = 6.921$  Å within its homogeneity range from 30 to 34.5 at.% Sc. These data are in agreement with the data of Markiv et al.

Markiv et al. (1978) published also the Sc-Ni phase diagram in the range 0–80 at.% Sc. These authors confirmed the five binary compounds ScNi<sub>5</sub>, Sc<sub>2</sub>Ni<sub>7</sub>, ScNi<sub>2</sub>, ScNi and Sc<sub>2</sub>Ni, which were earlier synthesised and structurally determined (table 5). There was a disagreement between the data of Goebel and Rosen (1968) and Markiv et al. concerning the homogeneity range of the ScNi<sub>2</sub> phase. Goebel and Rosen reported it from 27.2 to 33.4 at.% Sc at 1000°C, while Markiv et al. fixed the lower and upper limits at 30 and 36 at.% Sc ( $a = 6.866$ – $6.938$  Å), respectively.

Maslenkov and Braslavskaya (1984) reinvestigated part of the Sc-Ni phase diagram in the range 0–36 at.% Sc. Their data are in excellent agreement with the data of Markiv et al. The temperatures of the phase transitions differ no more than 5–10°C at temperatures >1000°C, which is within the experimental error limits. ScNi<sub>2</sub> forms a homogeneous solid solution in the range of 31–35 at.% Sc as reported by Maslenkov and Braslavskaya. The lattice spacing displays a positive deviation from Vegard's rule and changes from  $a = 6.871$  to  $a = 6.920$  Å as determined from a plot of  $a$  vs. concentration. Finally, the same authors, Braslavskaya and Maslenkov (1987), established the occurrence of polymorphism for ScNi<sub>5</sub> and reinvestigated the crystal structure of ScNi<sub>5</sub> and Sc<sub>2</sub>Ni<sub>7</sub> phases (table 5). The data of Braslavskaya and Maslenkov for lattice spacings of ScNi<sub>5</sub> (HT) and especially of Sc<sub>2</sub>Ni<sub>7</sub> differ remarkably from the data of Goebel and Rosen (table 5). The reason for that is unknown.

The revised Sc-Ni phase diagram is presented in fig. 8. This figure includes the data of Markiv et al. in the range >36 at.% Sc and the data of Maslenkov and Braslavskaya, and Braslavskaya and Maslenkov in the range 0–36 at.% Sc. The temperatures of phase transitions of pure components are in agreement with the accepted values.

Fig. 8. The Sc-Ni phase diagram in the range 0-80 at.% Sc.

### 2.9. Sc-M (*M* = platinum group element) systems

The Sc-Ru phase diagram has been investigated by Savitskii et al. (1971b). They confirmed the existence of the two binary compounds ScRu<sub>2</sub> and ScRu (table 6) and synthesised a third one with an unknown structure. Chabot et al. (1980a) determined the composition of the latter phase as Sc<sub>11</sub>Ru<sub>4</sub> as well as its structure (table 6). The same group of authors, Chabot et al. (1980b), synthesised a fourth binary compound in the system with an approximate composition Sc<sub>6</sub>Ru and a cubic structure. Finally five years later Cenzual et al. (1985) established its real composition, Sc<sub>57</sub>Ru<sub>13</sub>, and the crystal structure (table 6). Other data, which also support the reinvestigation of this phase diagram, are the two reported sets of values for the lattice spacings of the ScRu<sub>2</sub> compound (table 6). They indicate that ScRu<sub>2</sub> has, perhaps, a homogeneity range.

Khorujaya et al. (1995) reported on the Sc-Rh phase diagram which is presented in fig. 9. These authors found extended homogeneity ranges for ScRh and ScRh<sub>3</sub> compounds which explained the different values of the lattice spacings for these phases reported earlier by different authors (table 6). However, it is unknown to which composition these published values belong. Three other binary compounds Sc<sub>2</sub>Rh, Sc<sub>3</sub>Rh and Sc<sub>57</sub>Rh<sub>13</sub> exist in this system (table 6).

The Sc-Pd phase diagram was established by Savitskii et al. (1971c,d). Gschneidner (1975) presented a revised phase diagram, based primarily on these data. He corrected the composition of earlier known Sc<sub>2</sub>Pd phase, which was shown in the original diagram at the composition "Sc<sub>3</sub>Pd<sub>2</sub>" and changed the temperatures of phase transitions for pure components to the presently accepted values. Gschneidner presented also the arguments in favour of occurrence of the broad homogeneity range for ScPd<sub>3</sub> (see values of lattice spacing in table 6) and the much higher solubility of scandium in solid palladium. The different values of the lattice spacing reported for Sc<sub>2</sub>Pd (see table 6) may also indicate the existence of a homogeneity range of that phase too. Finally, Savitskii et al. established very

approximately the whole liquidus curve except in the concentration range 90–100 at.% Sc. Thus, a reinvestigation of phase diagram would be necessary. Altogether there exist five binary compounds in this system. Their characteristics are presented in table 6.

As yet no phase diagram is known for the Sc–Os system. However there are data for three binary compounds; these data are presented in table 6. Various values reported for the lattice spacings of ScOs<sub>2</sub> suggest a homogeneity range for that phase.

The Sc–Ir phase diagram, which is shown in fig. 10, is based on the results reported by Eremenko et al. (1994). Five of seven binary compounds have been confirmed, and two new compounds Sc<sub>2</sub>Ir and ScIr<sub>3</sub> have been synthesised by the authors. The crystal structures of all of them are known and given in table 6. The lattice spacings of several of these compounds reported by Eremenko et al. are in excellent agreement with the earlier reported data (see table 6). However in the case of the compound Sc<sub>11</sub>Ir<sub>4</sub> with a constant composition there is remarkably large difference in the values of lattice spacing, which is not understood.

Four intermetallic scandium–platinum compounds have been prepared and their crystal structures were determined (table 6). Only a few of the phase equilibria in the Sc–Pt phase diagram up to 50 at.% Sc were determined by Savitskii et al. (1978a). The solubility of

Fig. 9. The Sc-Rh phase diagram.

Fig. 10. The Sc-Ir phase diagram.

scandium in solid platinum is about 10 at.%. In the single invariant phase transformation shown in the original diagram at  $1850 \pm 25^\circ\text{C}$ , four phases, namely  $L$ ,  $\text{Pt}(\text{Sc})$ ,  $\text{ScPt}_3$  and  $\text{ScPt}$ , are involved, which is in contradiction with the Gibbs phase rule. The slight variations of lattice spacing for  $\text{ScPt}_3$  (see table 6) may be due to the result of a homogeneity range similar to that in the cases of  $\text{ScRh}_3$  and  $\text{ScIr}_3$ . However, in the figure of the phase diagram presented by Savitsky et al.  $\text{ScPt}_3$  has a constant composition. Thus, the Sc–Pt phase diagram is too tentative and needs additional investigation.

#### 2.10. Sc– $M$ ( $M = 1B$ element) systems

Savitskii et al. (1970) and Naumkin et al. (1971) were the first to study the Sc–Cu phase diagram. Two binary compounds  $\text{ScCu}$  and  $\text{ScCu}_2$  which were known earlier were confirmed, and a third one,  $\text{ScCu}_4$ , was reported for the first time. Markiv et al. (1978) reinvestigated the phase diagram in the range 0–80 at.% Sc. In general the data presented in these three papers are in good agreement with each other except for the way of formation of the  $\text{ScCu}_2$  compound and its melting temperature, and the homogeneity range of the  $\text{ScCu}_4$  phase. Savitskii et al. and Naumkin et al. established the peritectic formation of  $\text{ScCu}_2$  at  $890^\circ\text{C}$ , while Markiv et al. reported that it is congruently melting at  $990^\circ\text{C}$ . The  $\text{RCu}_2$  compounds with the heavy rare earths Gd, Dy or Y are also congruently melting phases (Massalski 1990). It is known that scandium resembles the alloying behaviour of these rare earths. For that reason we prefer the data of Markiv et al. concerning the way and temperature of formation of the  $\text{ScCu}_2$  compound. We think that the data of Markiv et al. who reported the homogeneity range for  $\text{ScCu}_4$  compound from 19 to 23 at.% Sc are more correct. The Cu-rich side of the  $\text{ScCu}_4$  phase was determined by microprobe analysis as 18.6 at.% Sc (see Kotur et al. 1996a). Its crystal structure is unknown (table 7). All attempts to solve its structure using powder or single-crystal methods were unsuccessful since the phase is terribly sensitive to mechanical grinding (see Kotur et al. 1996a). The Sc–Cu phase diagram is presented in fig. 11. It is based primarily on the data of Savitskii et al. and Naumkin et al., and in some regions, as mentioned above, on the data of Markiv et al. However, there are also indications that the melting temperature of  $\text{ScCu}_4$  is higher than  $1000^\circ\text{C}$  (Kotur et al. 1996a). Thus, the phase diagram needs an additional investigation in the range 15–35 at.% Sc as well as in the Sc-rich region (>80 at.% Sc). An extended list of references on this system can be found in the paper by Subramanian et al. (1988).

The solubility of scandium in silver was investigated by Gschneidner et al. (1970) who presented the part of Sc–Ag phase diagram in the range 0–12 at.% Sc. The phase diagram in the concentration region 0–85 at.% Sc has been established by Stapf et al. (1975). Three earlier known binary compounds have been confirmed. Their characteristics are presented in table 7. Stapf et al. reported the eutectic temperature of  $910^\circ\text{C}$  between the Ag solid solution and  $\text{ScAg}_4$ , and the composition of the melt at that temperature containing 10 at.% Sc. These data do not agree with the data of Gschneidner et al. who reported a maximum solubility of 10.5 at.% Sc in solid Ag at the eutectic temperature of  $926^\circ\text{C}$ . We prefer these latter data since they were obtained from a larger number of samples.

Fig. 11. The Sc-Cu phase diagram.

This assumption required the shifting of the  $L + \text{ScAg}_2 \leftrightarrow \text{ScAg}_4$  peritectic temperature by 16°C of the data of Stapf et al. as well as the shifting of the composition of the eutectic.

Fig. 12. The Sc-Ag phase diagram.

The Sc-Ag phase diagram presented in fig. 12 is based primarily on the data of Stapf et al. and the above mentioned modification based on the data of Gschneidner et al. The temperatures of the Sc phase transitions are indicated too, although the Sc-rich part of the phase diagram needs to be determined.

The 0–14 at.% Sc part of the Sc-Au phase diagram was reported over three decades ago (Rider et al. 1965). The figure is also presented by Gschneidner (1975). The maximum solubility of scandium (8.8 at.%) in solid gold occurs at the eutectic temperature of 1040°C. Four binary compounds have been synthesised in the system. Their crystal structure data are presented in table 7.

### 2.11. Sc-M ( $M = 2B$ element) systems

The Sc-Zn phase diagram in the range 0–60 at.% Sc has been recently reported by Palenzona and Manfrinetti (1997); it is presented in fig. 13. Four of the earlier known binary compounds have been confirmed by them and a new one, Sc<sub>13</sub>Zn<sub>58</sub> has been added. The crystal structure data are given in table 8. Earlier, Kripyakevich et al. (1966) reported the existence of a cubic compound with the lattice spacing 13.79 Å and the approximate composition Sc<sub>2</sub>Zn<sub>7</sub>. The authors identified the structure to be closely related to the Ru<sub>3</sub>Be<sub>17</sub> type. Andrusyak et al. (1989) using single-crystal structure investigation corrected its composition to Sc<sub>3</sub>Zn<sub>17</sub> and established that it belongs to the Ru<sub>3</sub>Be<sub>17</sub> structure type (table 8).

Palenzona and Manfrinetti (1996) investigated the Sc-Cd phase diagram in the range 0–70 at.% Sc, which is shown in fig. 14. The Sc-rich part of the phase diagram is drawn schematically since it has not been investigated experimentally and further investigations are necessary. Scandium is practically insoluble in solid cadmium. The solubility of cadmium in βSc is comparatively high, as can be established from the change of the variation of the lattice parameter which varies from 3.73 Å for pure Sc to 3.58 Å in

Fig. 13. The Sc-Zn phase diagram in the range 0-60 at.% Sc.

Fig. 14. The Sc-Cd phase diagram in the range 0-70 at.% Sc.

a quenched two-phase alloy containing 30 at.% Cd (Palenzona and Manfrinetti). These authors confirmed the existence of two known binary compounds, namely ScCd and ScCd<sub>2</sub>, and synthesised a third one, ScCd<sub>7</sub>. The crystal structures of all these compounds have been determined and are given in table 8. The data given by the different authors for the lattice spacings of these compounds are in good agreement (see table 8). The ScCd phase is characterised by the homogeneity region ranging from 50 to about 62 at.% Sc. The lattice spacing changes from  $a = 3.510 \text{ \AA}$  for the equiatomic composition to  $a = 3.524 \text{ \AA}$  for the Sc-rich composition (Palenzona and Manfrinetti).

Only two binary compounds, ScHg and ScHg<sub>3</sub>, are known in the Sc-Hg phase diagram. Their crystal structures have been determined by Laube and Nowotny (1963b) (table 8).

### 2.12. Sc-X (X = 3B element) systems

The Sc-B phase diagram has been published by Spear (1976, 1977). Figure 15 presents the Sc-B phase diagram based on these papers. Two binary compounds occur in this system, namely ScB<sub>12</sub> and ScB<sub>2</sub>. Earlier it was claimed that there exist two other B-rich compounds ScB<sub>4</sub> and ScB<sub>6</sub>, however already Peshev et al. (1970) could not confirm the existence of these two phases. The published data for the crystal structure of ScB<sub>2</sub> phase and its lattice spacings are in good agreement with each other (see table 9). However, two different crystal structures have been reported for the ScB<sub>12</sub> compound. Przybylska et al. (1963) found its structure to be isotypic with the cubic UB<sub>12</sub>. A single-crystal investigation by Matkovich et al. (1965) revealed however that the ScB<sub>12</sub> structure is tetragonal, isotypic with ThMn<sub>12</sub> (SG *I4/mmm*,  $a=5.22$ ,  $c=7.35$  Å). Its pseudocubic

Fig. 15. The Sc-B phase diagram.

tetragonal structure was confirmed also by Peshev et al. (1970) and by Callmer (1978) ( $a = 5.2347$ ,  $c = 7.3583$  Å). However a recent single-crystal investigation of ScB<sub>12</sub> by Bruskov et al. (1988) confirmed the cubic UB<sub>12</sub>-type structure (table 9). It seems that this question needs additional investigation. Perhaps ScB<sub>12</sub> occurs in two polymorphic modifications, but this does not agree with the presented phase diagram.

A detailed reference list on the scandium-boron alloys and their properties can be found in the reviews of Gschneidner (1975) and Spear and Liao (1990).

The Sc-Al phase diagram has been established by Naumkin et al. (1965). The Al-rich region was later refined by Drits et al. (1973). A phase diagram based on these papers is presented in the review of Gschneidner and Calderwood (1989a). In this paper and in the review of Gschneidner (1975) an extended list of references has been given. The solubility of scandium in solid aluminium does not exceed 0.22 at.% (Drits et al.), whereas Sc dissolves about 4 at.% Al (Naumkin et al.). Four binary compounds of constant composition occur in the system. Their compositions and characteristics are given in table 9. Schob and Parthé (1965) reported the CsCl structure type (SG  $Pm\bar{3}m$ ) for ScAl ( $a = 3.450$  Å) and noticed several extra lines in its X-ray patterns. Schuster and Bauer (1985) during an investigation of the Sc-Al-N ternary system determined that pure ScAl had the CrB-type structure. These authors claimed that either oxygen or nitrogen (or both) can stabilize the CsCl structure in the Sc-Al alloys.

There exist two variants of the Sc-Ga phase diagram in the literature. The first one was reported by Markiv et al. (1977) who investigated only 13 binary alloys within

the concentration range of 35–68 at.% Ga, which is only half of the number of alloys investigated by Yatsenko et al. (1979) (see below). From this investigation Markiv et al. (1977) concluded that there exist seven binary compounds. Three of them, Sc<sub>5</sub>Ga<sub>3</sub>, Sc<sub>2</sub>Ga<sub>3</sub> and ScGa<sub>3</sub>, were reported to melt congruently at temperatures 1380, 1130 and 1090°C, respectively. The others, Sc<sub>2</sub>Ga, Sc<sub>5</sub>Ga<sub>4</sub>, ScGa and ScGa<sub>2</sub>, are formed by peritectic reactions at 1065, 1240, 1080 and 1070°C, respectively. In this paper and in the following papers (Belyavina and Markiv 1980a, 1992, Markiv et al. 1981, 1987, 1989), the same group of scientists presented results of crystal structure investigations of the above mentioned gallides and also reported about the synthesis of an extra binary compound Sc<sub>3</sub>Ga<sub>2</sub>. Markiv et al. (1981) corrected the composition of the earlier reported “Sc<sub>2</sub>Ga<sub>3</sub>” compound which they subsequently found to be Sc<sub>3</sub>Ga<sub>5</sub>. The crystal structure data are given in table 9. Belyavina and Markiv (1992) reinvestigated the structure of the Sc–Ga alloys in the range 30–38.5 at.% Ga. The Sc<sub>2</sub>Ga compound has a narrow homogeneity range from 33 to 35 at.% Ga. Its monoclinic crystal structure is related to Mn<sub>5</sub>Si<sub>3</sub> type.

Fig. 16. The Sc-Ga phase diagram.

In the alloys with the content 36–8.5 at.% Ga they observed two hexagonal phases which they presented as  $h$ -Sc<sub>5</sub>Ga<sub>3</sub> and  $r$ -Sc<sub>5</sub>Ga<sub>3</sub> with the lattice spacings  $a=8.048$ – $8.062$  and  $c=6.112$ – $6.073$  Å, and  $a=8.084$  and  $c=5.958$  Å respectively. The pure  $r$ -Sc<sub>5</sub>Ga<sub>3</sub> was observed in a specimen with 36 at.% Ga and heat treated at 800°C. Thus, the composition of the phase is shifted from stoichiometry 5:3 (37.5 at.% Ga). This compound appears at temperatures lower than 1000°C, and its structure was determined to be of the Mn<sub>5</sub>Si<sub>3</sub> type. The crystal structure of the  $h$ -Sc<sub>5</sub>Si<sub>3</sub> phase, which is observed at high temperatures with the content of about 38 at.% Ga, has not been established and needs additional investigation. The structure of another compound isotypic with  $h$ -R<sub>5</sub>Ga<sub>3</sub> (R=Y, Tm, Lu) reported by Markiv and Belyavina (1992) is also unknown, however, as stated by Markiv and Belyavina the structure of these compounds should closely be related to the Mn<sub>5</sub>Si<sub>3</sub> type structure.

A second variant of the Sc-Ga phase diagram was presented by Yatsenko et al. (1979). These authors investigated 28 alloys over the whole concentration region of the system. Figure 16 presents the Sc-Ga phase diagram based on the data of Yatsenko et al. The two variants of the Sc-Ga phase diagram considerably differ from each other. Yatsenko et al. observed only five binary compounds in the system (see fig. 16). For three of them, ScGa<sub>3</sub>, Sc<sub>5</sub>Ga<sub>3</sub> and ScGa, they determined the crystal structure. These data perfectly agree with the data of Markiv et al. But in general the disagreement between the two reported versions is drastic. Such disagreement is hard to explain as the two groups of scientist used practically the same experimental methods: differential thermal, X-ray and microscopic analyses. Markiv et al. used also the microprobe analysis and Yatsenko et al. performed also microhardness measurements on their samples. These diverging results strongly suggest that the Sc-Ga phase diagram needs to be reinvestigated.

The Sc-In phase diagram was determined by Yatsenko et al. (1983). Earlier the part of the phase diagram in the range 0–40 at.% In was proposed by Gardner et al. (1968), but their data were tentative. Yatsenko et al. confirmed the compositions and crystal structures

Fig. 17. The Sc-In phase diagram.

of three binary scandium indides,  $\text{ScIn}_3$ ,  $\text{Sc}_2\text{In}$  and  $\text{Sc}_3\text{In}$ , which had been synthesised earlier, and observed three new compounds of the tentative compositions  $\text{Sc}_3\text{In}_5$ ,  $\text{ScIn}$  and  $\text{Sc}_5\text{In}_3$  with unknown structures.

Recently Palenzona et al. (1996) reinvestigated the Sc-In phase diagram in the range 30–100 at.% In. The compounds  $\text{Sc}_3\text{In}_5$  and  $\text{Sc}_5\text{In}_3$  could not be confirmed and were replaced by  $\text{ScIn}_2$  and  $\text{ScIn}_{1-x}$ , respectively. In addition four other binary phases have been confirmed. Their characteristics are given in table 9. The temperatures of the phases transitions reported by Palenzona et al. are in average 5 to 20°C higher than those reported by Yatsenko et al. with the exception of the temperature for the peritectic formation of  $\text{ScIn}_{1-x}$  which is 50°C lower than that of the corresponding “ $\text{Sc}_5\text{In}_3$ ” phase reported by Yatsenko et al. Figure 17 presents the phase diagram based on the data of Palenzona et al. (1996) (in the range 0–70 at.% Sc) and those of Yatsenko et al. (1983) (in the range 70–100 at.% Sc). Gschneidner (1975) reviewed the physical properties of Sc-In compounds.  $\text{Sc}_3\text{In}$  is a well known weak ferromagnetic compound with a Curie temperature near 6 K. Since it has been considered as a prototype of an intermetallic compound where spin fluctuations play an important role its physical properties are discussed in sect. 6.

Sabirzyanov (1988) was the only scientist who investigated the interaction of scandium with thallium. He established the phase diagram shown in fig. 18. The investigation was carried out by means of thermal, X-ray and microscopic analyses. He also measured the magnetic susceptibility of the alloys. Seven binary compounds occur in the system. Sabirzyanov determined the crystal structure of five of them (table 9). For two phases with unknown structures the compositions of  $\text{Sc}_3\text{Tl}$  and  $\text{ScTl}_2$  are given as the most likely ones. The homogeneity range for  $\text{Sc}_5\text{Tl}_{3-3.85}$  reaches 6 at.% at 1262°C. The limits of solubility of thallium in  $\beta\text{Sc}$  and  $\alpha\text{Sc}$  are  $18 \pm 1$  at.% and  $11 \pm 1$  at.%, respectively. The data concerning the temperatures of the phase transitions, the compositions and crystal structures of the compounds (except lattice spacings) were also presented by Sabirzyanov (1989); however, the phase diagram was not shown.

Fig. 18. The Sc-Tl phase diagram.

Fig. 19. The Sc-C phase diagram in the range 20-100 at.% Sc.

2.13. Sc-X (X = 4B element) systems

Many papers have been dedicated to the investigation of interaction of scandium with carbon. The early papers which appeared before 1973 have been reviewed by Gschneidner (1975) and Gschneidner and Calderwood (1986c). In total seven compounds have been reported to occur in this system, however, the majority of them were not confirmed. Gordijchuk et al. (1981) first reported on the Sc-C phase diagram in the range 20-100 at.% Sc and refined it afterwards (Gordijchuk 1987). The phase diagram presented in fig. 19 is based mainly on the latter data; there are only three binary compounds. Their

crystal structure data are presented in table 10. One of the phases,  $\text{Sc}_4\text{C}_3$ , exists in two polymorphic modifications. The data of Gorgijchuk agree with the results of Krikorian et al. (1969a) who also observed that  $\text{Sc}_4\text{C}_3$  (ST anti- $\text{Th}_3\text{P}_4$ , SG *I43d*,  $a = 7.207 \text{ \AA}$ ) remained stable when heated to  $1500^\circ\text{C}$ . Its X-ray pattern changed when heating the sample up to  $1600^\circ\text{C}$ . Krikorian et al. (1969b) reported also about a bcc phase with the approximate composition  $\text{Sc}_{13}\text{C}_{10}$  ( $\sim 56.5 \text{ at.\% Sc}$ ,  $a = 8.5268 \text{ \AA}$ ). It was synthesised after annealing the  $\text{Sc}_4\text{C}_3$  sample with an addition of germanium. However the Ge atoms are not involved into the structure of this scandium carbide. Possibly Krikorian et al. obtained the high temperature phase of  $\text{Sc}_4\text{C}_3$  ( $\beta$ ) reported by Gordijchuk. Jedlichka et al. (1971) were the first to determine the composition and the crystal structure of the scandium carbide with the highest Sc content, which was earlier reported by Krikorian et al. (1969a) as “ $\text{ScC}_{1.2-1.3}$ ”. Jedlichka et al. (1971) determined its composition as  $\text{Sc}_{15}\text{C}_{19}$  (ST  $\text{Sc}_{15}\text{C}_{19}$ , SG *P42<sub>1c</sub>*,  $a = 7.50$ ,  $c = 15.00 \text{ \AA}$ ). Recently Pöttgen and Jeitschko (1991) reinvestigated the structure of  $\text{Sc}_{15}\text{C}_{19}$  using a single crystal and reported its composition as  $\text{Sc}_3\text{C}_4$ . The tetragonal unit cell of  $\text{Sc}_3\text{C}_4$  contains two additional carbon atoms in comparison to the  $\text{Sc}_{15}\text{C}_{19}$  structure. Its lattice spacings are given in table 10. Maybe that these two investigated single crystals  $\text{Sc}_3\text{C}_4$  (42.9 at.% Sc) and  $\text{Sc}_{15}\text{C}_{19}$  (44.1 at.% Sc) can be treated in favour of occurrence of homogeneity range of this compound reported by Gordijchuk (see fig. 19). Gordijchuk determined its homogeneity range from 43.5 to 45.7 at.% Sc and the lattice spacings changing from  $a = 7.53$ ,  $c = 15.04 \text{ \AA}$  to  $a = 7.51$ ,  $c = 15.51 \text{ \AA}$ . Thus, to clarify the conflicting data additional investigations of the system, particularly in the range 40–80 at.% Sc, have to be carried out.

Although three binary scandium silicides,  $\text{Sc}_5\text{Si}_3$ ,  $\text{ScSi}$  and  $\text{Sc}_3\text{Si}_5$ , were obtained and structurally investigated already in the early 1960s (table 10), a Sc–Si phase diagram was only presented in 1988. It is shown in fig. 20. The data are taken from Eremenko et al. (1988) with corrections for the phase transition temperatures of pure components to the presently accepted values. For scandium the difference between the reported melting temperature ( $1615^\circ\text{C}$ ) and the  $\beta\text{Sc} \leftrightarrow \alpha\text{Sc}$  transition temperature ( $1430^\circ\text{C}$ ) and the corresponding present temperatures  $1541$  and  $1337^\circ\text{C}$  is rather large. In the case of silicon the difference in the melting temperature ( $1412^\circ\text{C}$  reported and  $1414^\circ\text{C}$  accepted) was within the experimental error. Eremenko et al. confirmed the data of Bodak et al. (1976) and Kotur (1977a) that the binary phase with the highest Si content exists only at high temperature (see fig. 20). Bodak et al. and Kotur observed that phase only in the as cast alloys. After heat treatment at  $800^\circ\text{C}$  for 340 h this phase totally decomposed to Si and ScSi. There is a disagreement between the data about the composition of the highest silicon-containing scandium silicide. Gladyshevsky and Emes-Misenko (1963) reported it as  $\text{Sc}_3\text{Si}_5$  (62.5 at.% Si), Schob and Parthé (1964b) found it to have the homogeneity range from 60 (composition  $\text{Sc}_2\text{Si}_3$  or  $\text{ScSi}_{1.5}$ ) to 62.5 at.% Si (composition  $\text{Sc}_3\text{Si}_5$  or  $\text{ScSi}_{1.67}$ ), whereas Eremenko et al. claimed a constant composition  $\text{ScSi}_{1.5}$ . For the reported lattice spacings for this phase, it is given as  $\text{ScSi}_{2-x}$  in table 10.

Recently Kotroczo and McColm (1994) established the phase equilibria for rapidly cooled Sc–Si alloys (cooling rate  $150\text{--}200^\circ\text{C/s}$ ). Their phase diagram shows many similarities with that of Eremenko et al. But in general the liquid boundaries and

the nonvariant reactions were 10 to 110°C and in one case (for peritectic reaction  $L + \text{ScSi} \leftrightarrow \beta\text{ScSi}_{2-x}$ ) even 525°C higher than those reported by Eremenko et al. Kotroczo and McColm reported the highest silicon-containing silicide as having the homogeneity range  $\text{ScSi}_{1.22-1.67}$  (55–62.5 at.% Si), a polymorphic transition in the temperature range 1325–1350°C, and being stable down to the room temperature. Neither Kotroczo and McColm nor Eremenko et al. obtained pure  $\text{AlB}_2$ -type structure specimens of this silicide. They observed in the X-ray patterns the presence of a nonstoichiometric  $\text{AlB}_2$ -type

Fig. 21. The Sc-Ge phase diagram.

structure, however, together with extra weak lines. Eremenko et al. determined the lattice spacings of this  $AlB_2$ -type phase as  $a = 3.654$ ,  $c = 3.87$  Å. Kotroczo and McColm observed an increase of the lattice parameters from  $a = 3.656$ ,  $c = 3.872$  Å to  $a = 3.665$ ,  $c = 3.880$  Å as the silicon content increases. An indexing of almost all lines of the patterns was possible assuming an orthorhombic unit cell with  $a = 8.27(9)$ ,  $b = 8.69(7)$ ,  $c = 9.98(9)$  Å. The fourth binary silicide  $Sc_5Si_4$  ( $P$ , 1920°C) was observed by Kotroczo and McColm in rapidly cooled alloys. Its X-ray pattern was indexed as an orthorhombic cell with  $a = 6.78(2)$ ,  $b = 13.11(4)$ ,  $c = 7.03(1)$  Å. In our opinion these data indicate that the  $Sm_5Ge_4$  structure type as a possible structure for  $Sc_5Si_4$ , which is structure for the corresponding scandium germanide  $Sc_5Ge_4$  (see table 10).

Okamoto (1992) mentioned the thermodynamical inconsistency of the liquidus curve in the Sc-Si phase diagram of Eremenko et al. (see fig. 20, between 30 and 45 at.% Si). Therefore a new investigation of the Sc-Si phase diagram in the range 40–65 at.% Si is advisable.

The Sc-Ge system was experimentally investigated by Eremenko et al. (1981). Figure 21 displays the Sc-Ge phase diagram based on these data. The solubility of germanium in  $\beta$ Sc is less than 0.5 at.% whereas in solid  $\alpha$ Sc it is more than 1 at.% but this value is not yet exactly determined. The solubility of scandium in germanium is less than 1 at.%. Three germanides, namely  $Sc_5Ge_3$ , ScGe and ScGe<sub>2</sub> were known before Eremenko et al. synthesised two others,  $Sc_5Ge_4$  and  $Sc_{11}Ge_{10}$ . The data from different authors about the crystal structure of scandium germanides are in general agreement (see table 10). Only in

Fig. 22. The Sc-Sn phase diagram in the range 0–70 at.% Sc.

the case of  $\text{Sc}_{11}\text{Ge}_{10}$  is there a considerable difference in the reported  $a$  lattice spacings, while the  $c$  values are identical.

Palenzona and Manfrinetti (1995) published the Sc-Sn phase diagram in the range 0–70 at.% Sc which is presented in fig. 22. Earlier only the experimental data by Eremenko et al. (1990) existed, and they reported that  $\text{Sc}_5\text{Sn}_3$  melts congruently at 1775°C. These data were confirmed by Palenzona and Manfrinetti (1995). Four binary stannides occur in the system. Two of them,  $\text{ScSn}_2$  and  $\text{Sc}_6\text{Sn}_5$  have been prepared and structurally investigated by Palenzona and Manfrinetti for the first time. These authors did not mention the data of Kotur and Derkach (1994) who reported that  $\text{ScSn}$  has the CsCl structure type. Since scandium-tin alloys are extremely oxidizable the  $\text{ScSn}$  phase could not be obtained in pure state. Palenzona and Manfrinetti did not determine the crystal structure of  $\text{ScSn}$ , however they mentioned the rather simple character of its powder X-ray pattern. The crystal structure characteristics of scandium stannides are presented in table 10.

The Sc-Pb phase diagram has been determined by Palenzona and Manfrinetti (1995) in the range 0–70 at.% Sc (see fig. 23). The Sc-rich part of this system (as well as the Sc-Sn system, discussed above) has not been investigated because of the high melting temperatures of the corresponding alloys and contamination of them by molybdenum which was used as container material during preparation of the samples. Two binary compounds occur in the system (table 10), one of them,  $\text{Sc}_5\text{Pb}_3$  was known before the investigation of Palenzona and Manfrinetti.

#### 2.14. Sc-X ( $X = \text{P}, \text{As}, \text{Sb}, \text{Bi}$ ) systems

There is no information in the literature about the binary phase diagrams of scandium with the 5B elements (P, As, Sb, Bi). Although in each of the systems from one to four binary

Fig. 23. The Sc-Pb phase diagram in the range 0-70 at.% Sc.

compounds have been synthesised and their crystal structures have been determined, there is no information about their melting temperatures and the way of formation (see table 11). The only exception are the data of Komissarova et al. (1965) who found that ScP has a melting temperature higher than 2000°C. Evidently some phases occur in two (Sc<sub>3</sub>P<sub>2</sub>) or three (Sc<sub>3</sub>As<sub>2</sub>) polymorphic modifications, but nothing is known about the temperatures of their phases transitions. Different values of lattice spacings observed for NaCl-type compounds (see table 11) may be originating from the homogeneity ranges of these phases or from scandium of different purity used by different groups of scientists. Additional investigations are necessary to clarify these data. Additional literature can be found in Gschneidner (1975), and Gschneidner and Calderwood (1986b, 1989b).

#### 2.15. Sc-X (X = Se, Te, Po) systems

Only a little information exists about the interaction of scandium with the elements of selenium subgroup (Se, Te and Po). No phase diagrams are available for any of these binary systems.

Two binary compounds have been synthesised in the Sc-Se system by different groups of scientists. The results presented in table 12 indicate the possibility of homogeneity ranges of these phases.

Men'kov et al. (1959, 1961) synthesised two scandium tellurides and determined their crystal structures. The data of Men'kov et al. (1959) about the cubic  $\gamma'$ -Al<sub>2</sub>O<sub>3</sub>-type structure for the compound Sc<sub>2</sub>Te<sub>3</sub> had not been confirmed by a single-crystal structure investigation of that phase performed by White and Dismukes (1965) (see table 12). The latter authors obtained also a specimen of Sc<sub>2.3</sub>Te<sub>3</sub> composition isotypic with Sc<sub>2</sub>Te<sub>3</sub> with the lattice parameters  $a = 4.113$ ,  $c = 4.051$  Å. This result seems to indicate the occurrence

of a homogeneity range of this phase. There is a disagreement between the data reported about the crystal structure of another phase, namely ScTe. Brixner (1960) determined it as

hexagonal with the lattice spacings  $a = 6.728$ ,  $c = 8.360$  Å, however, Men'kov et al. (1961) reported it as isotypic with NiAs (see table 12). We consider the data of Men'kov et al. to be more reliable since the neighbouring scandium telluride,  $\text{Sc}_2\text{Te}_3$ , contains NiAs-type fragments in its structure.

In the literature there is information only about one binary compound occurring in the Sc–Po system. Its crystal structure data are given in table 12.

### 3. Ternary systems containing scandium

At the beginning of 1997 there was information on about 110 scandium ternary systems. Of these systems the phase equilibria have been investigated either for the entire concentration region of an isothermal section (or sometimes several sections), or for only in part of it. Selected alloys have been investigated in 85 of these ternary systems. A compilation of these data are given in table 13. As can be seen from that table, there is a considerable amount of data concerning the Sc–M–X ternaries, where M is a metal and X stands for a p-element. In this section we have arranged the data in the following subsections: Sc–M–B, Sc–M–Al, Sc–M–Ga, Sc–M–In, Sc–M–C, Sc–M–Si, Sc–M–Ge, Sc–M–Sn, and Sc–M–X with X=P, As, Sb, Bi and with X=Se, Te, Po. Since there is only a small amount of data available for the latter two cases, these subsections have not been subdivided. The last two subsections of the ternary systems include either two p-elements (Sc–X–X'), or two s-, d-, or f-metals (Sc–M–M'). If the isothermal section of a system is known from the literature it is shown in a figure together with a brief comment. If these isothermals have already been treated in one of the previous chapters of the *Handbook on the Physics and Chemistry of Rare Earths* then they are omitted. As in the previous section controversial data are mentioned separately and are critically evaluated as best we are able to do so.

Since there is only a small amount of data concerning the melting temperatures and the way of formation of ternary scandium intermetallics given in the literature, these data are not included in the tables which list the compositions and lattice parameters of ternary compounds. The reference from which the lattice parameters have been taken is listed first, and is followed by other references. The reference where the corresponding atomic coordinates of the structure have been published (if it is available) is italicized.

#### 3.1. Sc–M–B ternary systems

##### 3.1.1. Sc–La–B

The phase diagram of the Sc–La–B system is unknown. The solubility of scandium in  $\text{LaB}_6$  has been investigated by Tsolovski and Peshev (1972). It has been reported that the solubility reaches 0.5 mole fraction Sc, but according to the data of Kondrashov (1978) and Samsonov et al. (1979) the solubility is considerably lower. The limiting composition of the solid solution is  $\text{La}_{0.9}\text{Sc}_{0.1}\text{B}_6$ , and there is practically no change of the lattice parameter within this homogeneity range ( $\text{La}_{0.9}\text{Sc}_{0.1}\text{B}_6$  to  $\text{LaB}_6$ ).

##### 3.1.2. Sc–Cr–B

Zavalii and Mikhalenko (1989) reported about an investigation of the phase equilibria in the Sc–Cr–B system at 800°C (0–33.3 at.% Sc) and at 600°C (33.3–100 at.% Sc) but

Table 13  
Summary of information known about the Sc-M-X, Sc-M-M' and Sc-X-X' ternary phase diagrams

these authors did not present figures of these isothermal sections. CrB<sub>2</sub> dissolves up to 7 at.% Sc. One ternary compound ScCrB<sub>4</sub>, which is isotypic with YCrB<sub>4</sub>, occurs in the system, but the lattice spacings have not been reported (table 14).

Fig. 24. Sc–W–B, isothermal section at 1000°C.

### 3.1.3. Sc–W–B

Zavaliy and Mikhalenko (1989) briefly reported about an investigation of the phase equilibria in the Sc–W–B system at 1000°C (0–33.3 at.% Sc) and at 600°C (33.3–100 at.% Sc) without presenting the illustrations. The isothermal section at 1000°C, which is shown in fig. 24, is based on the data of Mikhalenko et al. (1991). Binary compound ScB<sub>2</sub> dissolves up to 10 at.% W. No ternary compounds were found.

### 3.1.4. Sc–Mn–B

The phase equilibria in the Sc–Mn–B system at 800°C (0–33.3 at.% Sc) and at 500°C (33.3–100 at.% Sc) have been investigated by Zavaliy and Mikhalenko (1989). Figures of these isothermal sections were not presented in the original paper. Scandium stabilises the high temperature binary phase MnB<sub>2</sub> at 800°C (ST AlB<sub>2</sub>). In the binary system it is stable in the temperature range 1827–1100°C. This solid solution has the homogeneity range of about 4–8 at.% Sc. One ternary compound, namely ScMnB<sub>4</sub> occurs in the system, but its lattice spacings have not been reported (table 14).

### 3.1.5. Sc–Re–B

Zavaliy and Mikhalenko (1989) have investigated the phase equilibria in the Sc–Re–B system at 1000°C (0–33.3 at.% Sc) and at 600°C (33.3–100 at.% Sc), but they did not show figures in their publication. The isothermal section of the phase diagram at 1000°C for the whole concentration region, which is shown in fig. 25, is based on the data of Mikhalenko et al. (1991). Scandium diboride dissolves up to 7 at.% Re. One ternary compound, Sc<sub>2</sub>ReB<sub>6</sub>, occurs in the system. Its characteristics are shown in table 14.

Fig. 25. Sc-Re-B, isothermal section at 1000°C. Ternary compound: (1)  $\text{Sc}_2\text{ReB}_6$ .

### 3.1.6. Sc-Fe-B

Stepanchikova and Kuz'ma (1981) studied isothermal sections of the Sc-Fe-B phase diagram at 700°C (0–50 at.% B) and at 1000°C (50–100 at.% B). In fig. 26 we corrected

Fig. 26. Sc-Fe-B, isothermal sections at 700°C (0–50 at.% B) and at 1000°C (50–100 at.% B). Ternary compound: (1)  $\text{ScFeB}_4$ .

the composition of the binary compound, earlier known as  $\sim\text{Sc}_7\text{Fe}$ , to  $\text{Sc}_{29}\text{Fe}_6$  (see sect. 2.8). One ternary compound was observed in this system, the data are given in table 14.

### 3.1.7. *Sc-Co-B*

The phase equilibria at 800 and 600°C in the Sc-Co-B system have been investigated by Stepanchikova (1979). The isothermal sections (depicted in fig. 27) are corrected for the homogeneity range of the binary compound  $\text{ScCo}_2$ , which was found to exist from 30 to 34.5 at.% Sc at 800°C (see sect. 2.8). Stepanchikova confirmed two ternary compounds which were known earlier and synthesized two new ternaries, namely  $\text{ScCo}_4\text{B}_4$  and  $\text{ScCoB}_4$  (table 14).

Fig. 27. Sc-Co-B, isothermal sections at 800°C (0–33.3 at.% Sc) and at 600°C (33.3–100 at.% Sc). Ternary compounds: (1)  $\text{Sc}_2\text{Co}_2\text{B}_6$ ; (2)  $\text{ScCo}_4\text{B}_4$ ; (3)  $\text{ScCo}_3\text{B}_2$ ; (4)  $\text{ScCoB}_4$ .

### 3.1.8. *Sc-Ni-B*

The isothermal section of Sc-Ni-B at 800°C has been established by Stepanchikova and Kuz'ma (1981). The occurrence of an earlier known ternary compound,  $\text{Sc}_3\text{Ni}_{20}\text{B}_6$  has been confirmed and four new ternary borides have been added (table 14). Zavalii et al. (1988) used a single crystal investigation for the refinement of the composition of the  $\sim\text{ScNi}_4\text{B}_4$  compound reported by Stepanchikova and Kuz'ma. According to the results of

Fig. 28. Sc-Ni-B, isothermal section at 800°C. Ternary compounds: (1)  $Sc_{3-4}Ni_{20-19}B_6$ ; (2)  $Sc_4Ni_{29}B_{10}$ ; (3)  $\sim Sc_4Ni_{15}B_6$ ; (4)  $ScNiB_4$ ; (5)  $ScNi_3B$ .

Zavaliy et al. it is  $Sc_4Ni_{29}B_{10}$ . Figure 28 displays the isothermal section of the Sc-Ni-B phase diagram, based on the data of Stepanchikova and Kuz'ma with corrected data of Zavaliy et al. and the recently observed homogeneity range for  $ScNi_2$  at 800°C (see sect. 2.8).

### 3.1.9. Sc-Ru-B

Ku et al. (1979) investigated part of the Sc-Ru-B phase diagram. Based on an X-ray analysis of the as-cast alloys, these authors observed the occurrence of the following two-phase equilibria:  $RuB-ScRuB_4$ , " $ScRu_2B_2$ "- $ScRuB_4$  and " $ScRu_2B_2$ "- $Ru_7B_3$ , as well as the metastable equilibria of  $ScRu_4B_4$  with  $ScRuB_4$ , " $ScRu_2B_2$ ",  $Ru_7B_3$  and  $RuB$ . The metastable  $ScRu_4B_4$  ternary phase decays during the homogenisation of alloys at temperatures between 800 and 1300°C. Later Rogl (1984a) refined the composition of " $ScRu_2B_2$ " and showed that the actual composition is  $Sc_2Ru_5B_4$ . The crystal structure data for all these ternary compounds are given in table 14.

### 3.1.10. Sc-Rh-B

In the study of the Rh-rich end of the Sc-Rh-B system Holleck (1977) established the existence of the solid solution of boron in the binary compound  $ScRh_3$  at 1300°C:  $ScRh_3B_{0-0.8}$  (ST  $AuCu_3$ ,  $a = 3.900-4.075 \text{ \AA}$ ). Evidently that solid solution can reach the composition  $ScRh_3B$  (ST  $CaTiO_3$ ).

### 3.1.11. *Sc-M-B* ( $M = Os, Ir$ )

There are no data yet available concerning the phase equilibria in the Sc–Os–B and Sc–Ir–B systems. Two ternary compounds in the Os system and three ternary compounds with Ir have been synthesized and their crystal structures determined (see table 14). The boron content in the compound  $ScIr_3B_{1-x}$  was not accurately determined because of the loss of some of the components during arc melting.

## 3.2. *Sc-M-Al ternary systems*

### 3.2.1. *Sc-Li-Al*

Berezina et al. (1986) investigated binary Al–(2.75–3) wt.% Li specimens alloyed with 0.1 to 0.7 wt.% Sc, which have been quenched from 580°C and subsequently homogenized at 175°C for 16 h. Their data indicate that a three-phase region  $Al + Al_3Li + Al_3Sc$  exists in the ternary system at 175°C.

### 3.2.2. *Sc-Mg-Al*

The part of the Sc–Mg–Al isothermal section (0–33.3 at.% Sc) at 400°C reported by Odinaev et al. (1989) is presented in fig. 29. No ternary compounds were observed. Turkina and Kuzmina (1976) investigated also the phase equilibria at 430°C and two polythermal sections in the Al-rich part of the phase diagram (alloys containing up to 26 wt.% Mg and up to 3 wt.% Sc). Three other quasibinary polythermal sections  $ScAl_2$ –Mg,  $ScAl_2$ – $Mg_2Al_3$  and  $ScAl_2$ – $Mg_{17}Al_{12}$  of the eutectic type, have been reported by Odinaev et al. (1991). All of the data are in good agreement with each other.

Fig. 29. Sc–Mg–Al, part of the isothermal section at 400°C (0–33.3 at.% Sc).

### 3.2.3. *Sc–Ca–Al*

Iandelli and Olcese (1985) investigated the alloys of the  $\text{ScAl}_2$ – $\text{CaAl}_2$  section in the Sc–Ca–Al ternary system. Between 800 and 900°C  $\text{CaAl}_2$  (ST  $\text{MgCu}_2$ ) dissolves 0.14 mole fraction of  $\text{ScAl}_2$ , whereas  $\text{ScAl}_2$  (ST  $\text{MgCu}_2$ ) dissolves 0.08 mole fraction of  $\text{CaAl}_2$ . These limited solid solutions are in two phase equilibria with each other. No ternary compounds were observed.

### 3.2.4. *Sc–Sr–Al*

The isothermal section of the Al corner of the Sc–Sr–Al phase diagram at 500°C (fig. 30) has been published by Trubniakova et al. (1987). The same group of scientists (Trubniakova and Ganiev 1989) reported on the polythermal section  $\text{SrAl}_4$ – $\text{ScAl}_3$ . The section is of eutectic type with a limited mutual solubility of the components. No ternary compounds occur in the investigated part of the system.

Fig. 30. Sc–Sr–Al, part of the isothermal section at 500°C (66.7–100 at.% Al).

### 3.2.5. *Sc–Ba–Al*

The isothermal section of Sc–Ba–Al at 500°C, which is based on the data of Alтынbaev et al. (1987), is presented in fig. 31. The immiscibility gap observed in the binary Sc–Ba system spreads deeply into the ternary system up to 56 at.% Al (dashed line in fig. 31). Six additional polythermal sections of the Sc–Ba–Al phase diagram, namely  $\text{ScAl}_2$ – $\text{BaAl}_4$ ,  $\text{ScAl}_2$ –Ba, ScAl–Ba,  $\text{ScAl}_3$ – $\text{BaAl}_4$ ,  $\text{ScAl}_2$ – $\text{BaAl}_2$ ,  $\text{ScAl}_2$ –BaAl have been investigated by the same group (Alтынbaev et al., 1990). No ternary compounds were observed.

### 3.2.6. *Sc–R–Al* ( $R = \text{La}, \text{Ce}, \text{Yb}$ )

Iandelli and Olcese (1985) investigated the alloys of the sections  $\text{ScAl}_2$ – $\text{RAl}_2$ . No ternary compounds were found in any of the three systems. At 800–900°C the mutual solubility of scandium in  $\text{LaAl}_2$  and lanthanum in  $\text{ScAl}_2$  is low. The boundary compositions of these solid solutions are:  $\text{Sc}_{0.04}\text{La}_{0.96}\text{Al}_2$  and  $\text{La}_{0.96}\text{Sc}_{0.04}\text{Al}_2$ .

In as-cast alloys  $\text{ScAl}_2$  and  $\text{CeAl}_2$  (ST  $\text{MgCu}_2$ ) are completely miscible in each other. The miscibility at 800°C decreases to about 0.15 mole fraction of  $\text{ScAl}_2$  in  $\text{CeAl}_2$  and about 0.19 mole fraction of  $\text{CeAl}_2$  in  $\text{ScAl}_2$ .

A continuous series of solid solutions have been observed in the as-cast alloys between isotypic  $\text{ScAl}_2$  and  $\text{YbAl}_2$ .

Fig. 31. Sc-Ba-Al, isothermal section at 500°C. The dashed line shows the extent of the Sc-Ba liquid immiscibility region.

### 3.2.7. Sc-R-Al ( $R = Y, Sm, Gd, Tb, Dy, Ho, Er, Tm, Lu$ )

The phase equilibria at 500°C and 800°C between  $ScAl_3$  and  $RAl_3$  been investigated by Zalutskaya et al. (1969) (systems with  $R = Y, Tb, Dy, Ho$  and  $Er$ ), Zalutskaya et al. (1970) (the system with  $R = Gd$ ), and Zalutskaya et al. (1974) (systems with  $R = Sm, Tm$  and  $Lu$ ). The terminal binary compounds have different stacking variants of cubic and hexagonal atomic layers: hexagonal,  $\gamma_2$  (ST  $Ni_3Sn$  or  $Mg_3Cd$ , 100% hexagonal stacking, for the compound  $GdAl_3$ ), cubic,  $\gamma_3$  (ST  $AuCu_3$ , 0% hexagonal stacking, for the compounds  $ScAl_3, ErAl_3, TmAl_3, LuAl_3$ ) and mixed variants  $\gamma_9$  (ST  $BaPb_3$ , 66.7% hexagonal stacking, for the compounds  $YAl_3, TbAl_3$ ),  $\gamma_4$  (ST  $TiNi_3$ , 50% hexagonal stacking, for the compound  $DyAl_3$ ) and  $\gamma_{15}$  (ST  $HoAl_3$ , 40% hexagonal stacking, for the compounds  $HoAl_3$  and  $DyAl_3$ ). Isotypic trialuminides are completely miscible in each other: Sc-Er-Al, Sc-Tm-Al and Sc-Lu-Al. In other ternary systems trialuminides form limited solid solutions.  $ScAl_3$  dissolves 10, 3, 3.75, 10.75, 15 and 18 at.% of Y, Sm, Gd, Tb, Dy and Ho, respectively. The solubility of Sc is 3.25, 2.5, 0.5, 2.5, 7.5 and 5.5 at.% in  $YAl_3, SmAl_3, GdAl_3, TbAl_3, DyAl_3$  (in both polymorphic modifications  $\gamma_4$  and  $\gamma_{15}$ ) and  $HoAl_3$ , respectively. The values of the lattice spacings of these solid solutions and figures of parts of the isothermal sections of the phase diagrams of these systems are available in the original papers and (except for the systems with Sm, Tm and Lu) in the review by Gschneidner (1975). Ternary compounds isotypic with  $TiNi_3$  ( $\gamma_4$ ) occur only in the Sc-Y-Al and Sc-Tb-Al systems. Their lattice spacings are presented in table 15. Visible differences between the phase equilibria occurring at 500 and 800°C have not been observed.

<sup>a</sup> For the composition ScNiAl.<sup>b</sup> For an unknown composition.3.2.8. *Sc–M–Al* (*M* = Ti, Zr, Hf)

Parts of the isothermal sections at 500°C of the Sc–M–Al (*M* = Ti, Zr, Hf) phase diagrams (66.7–100 at.% Al) reported by Kotur et al. (1989b) are presented in fig. 32. No ternary compounds were found. Binary scandium aluminides dissolve different quantities (in at.%) of the third element: ScAl<sub>3</sub> – 6 Ti, 10 Zr, 15 Hf; ScAl<sub>2</sub> – 5 Ti, 8 Zr, 13 Hf. The solubility of Sc in the aluminides of the 4A-elements does not exceed 5 at.%. These data are in good agreement with the data of Toropova et al. (1990) who reported on the phase equilibria in the Sc–Zr–Al system at 600°C. ScAl<sub>3</sub> and ZrAl<sub>3</sub> dissolve 10 at.% Zr and

Fig. 32. (a) Sc–Ti–Al, (b) Sc–Zr–Al, and (c) Sc–Hf–Al parts of the isothermal sections at 500°C (66.7–100 at.% Al).

5 at.% Sc, respectively. A two-phase region ( $\text{Sc}_{1-x}\text{Zr}_x\text{Al}_3 + \text{Zr}_{1-y}\text{Sc}_y\text{Al}_3$ ) and a three-phase region ( $\text{Al} + \text{Sc}_{1-x}\text{Zr}_x\text{Al}_3 + \text{Zr}_{1-y}\text{Sc}_y\text{Al}_3$ ) have been confirmed too.

### 3.2.9. Sc-Nb-Al

Shamrai et al. (1988) reported on the phase equilibria in the Sc-Nb-Al system at 200–800°C (fig. 33). Their data, which indicate a solubility of about 1 at.% Al in  $\alpha\text{Sc}$ , are in disagreement with the data of Naumkin et al. (1965) who report a solubility of about 4 at.% Al. There are no ternary compounds in the system. Binary aluminides dissolve less than 1 at.% of the third component.

Fig. 33. Sc-Nb-Al, phase equilibria at 200–800°C.

### 3.2.10. Sc-Cr-Al

Part of the Sc-Cr-Al isothermal section at 500°C (30–100 at.% Al), which is shown in fig. 34, has been investigated by Sokolovskaya et al. (1989). No ternary compounds were found.  $\text{ScAl}_3$  dissolves up to 11 at.% Cr. Other binary aluminides also dissolve large amounts of the third element, but there are no data available about lattice parameters of these solid solutions.

### 3.2.11. Sc-Mo-Al

Only a little information concerning the Sc-Mo-Al system is available. Cheldieva et al. (1989) investigated an isothermal section of the Al-rich part of the phase diagram at 500°C, and the polythermal sections between aluminides  $\text{ScAl}_3$  and  $\text{MoAl}_{12}$  and from the Al corner along the atomic ratio Mo:Sc=2:1 line, however no figure was given.

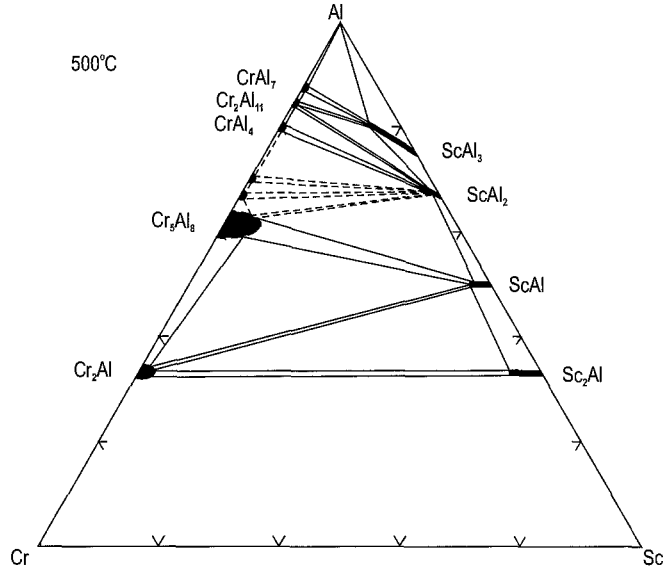

Fig. 34. Sc-Cr-Al, part of the isothermal section at 500°C (30–100 at.% Al).

They found that the binary scandium and molybdenum aluminides dissolve very small quantities of a third component. Ternary compounds have not been observed.

### 3.2.12. Sc-Mn-Al

Drits et al. (1984) reported about investigations of the Al-rich parts (96–100 at.% Al) of the Sc-Mn-Al isothermal sections at 500 and 600°C, and on the polythermal sections (Al+0.8 wt.% Sc)-Mn and Sc-(Al+0.8 wt.% Mn) in the regions 0–2.8 wt.% Mn and Sc, respectively. A three-phase area ( $\alpha$  solid solution (Al)+ScAl<sub>3</sub>+MnAl<sub>6</sub>) was found; however, no ternary compounds have been observed. Al dissolves less than 0.2 at.% Sc and 0.3 at.% Mn. Scandium appreciably decreases the solubility of manganese in aluminium.

### 3.2.13. Sc-Fe-Al

Part of the Sc-Fe-Al isothermal section (0–33.3 at.% Sc) at 500°C has been investigated by Zarechnyuk et al. (1970). This isothermal section is included in the review of Gladyshevsky et al. (1990). There are two ternary compounds with wide homogeneity ranges observed in the investigated part of the system (table 15). It is interesting to note that two isostructural compounds, ScFe<sub>2</sub> and ScFe<sub>1.35–0.30</sub>Al<sub>0.65–1.70</sub> (ST MgZn<sub>2</sub>), are in two-phase equilibrium with each other. Alloys of the ScAl<sub>2</sub>-ScFe<sub>2</sub> section at 800°C were also examined by Dwight et al. (1975). From the figure shown there it follows that ScAl<sub>2</sub> dissolves up to 6 at.% Fe whereas ScFe<sub>2</sub> dissolves only about 1 at.% Al. Dwight et al. also observed two ternary compounds ScFe<sub>1.96–1.4</sub>Al<sub>0.04–0.6</sub> (ST MgCu<sub>2</sub>) and ScFe<sub>1.37–0.2</sub>Al<sub>0.63–1.8</sub> (ST MgZn<sub>2</sub>) along the ScFe<sub>2</sub>-ScAl<sub>2</sub> pseudo-binary line. These

data are in agreement with the results of Sankar and Wallace (1976) who investigated the alloys of this section too. In addition Sankar and Wallace reported the composition ranges for these two ternary compounds at 1000°C:  $\text{ScFe}_{1.87-1.42}\text{Al}_{0.13-0.88}$  (ST  $\text{MgCu}_2$ ) and  $\text{ScFe}_{1.31-0.15}\text{Al}_{0.69-1.85}$  (ST  $\text{MgZn}_2$ ). However, no lattice spacings of these compounds are given in the papers of Dwight et al. (1975) and Sankar and Wallace (1976).

#### 3.2.14. *Sc-Co-Al*

Three ternary compounds have been synthesized and their crystal structures were determined (see table 15). Phase equilibria in this system have not been completely investigated.

#### 3.2.15. *Sc-Ni-Al*

Parts of two isothermal sections of the Sc-Ni-Al system have been studied by Goebel and Rosen (1968) (Ni corner at 1000°C) and Zarechnyuk and Rykhal (1977) (0–33.3 at.% Sc at 600°C). Their figures are presented in the review of Gladyshevsky et al. (1990). The data of Goebel and Rosen need to be completed in the region close to  $\text{Sc}_2\text{Ni}_7$  compound. Goebel and Rosen confirmed the ScNiAl ternary compound known from an earlier investigation by Teslyuk and Protasov (1965a) (ST  $\text{MgZn}_2$ ,  $a=5.12$ ,  $c=8.12$  Å), and they observed a new one,  $\text{ScNi}_2\text{Al}$  (ST  $\text{MnCu}_2\text{Al}$ ,  $a=6.02$  Å). Zarechnyuk and Rykhal synthesized the two ternary compounds  $\sim\text{ScNiAl}_4$ ,  $\sim\text{ScNiAl}_2$  and confirmed an extended homogeneity range for ScNiAl (see table 15). There are also the data of Markiv and Burnashova (1969) and Markiv and Storozhenko (1973) who reported an aluminide with the following composition  $\sim\text{Sc}_6\text{Ni}_7\text{Al}_{16}$  (ST  $\text{Th}_6\text{Mn}_{23}$  or  $\text{Mg}_6\text{Cu}_{16}\text{Si}_7$ ,  $a=12.16$  Å). Maybe this compound and the compound  $\sim\text{ScNiAl}_2$  identified by Zarechnyuk and Rykhal are the same.

#### 3.2.16. *Sc-Ru-Al*

Karatygina et al. (1974a) investigated part of the Sc-Ru-Al isothermal section at 600°C. One ternary compound  $\text{ScRu}_{0.92-0.32}\text{Al}_{1.08-1.68}$  with the  $\text{MgZn}_2$  structure type was found ( $a=5.27$ ,  $c=8.57$  Å for the composition  $\text{ScRu}_{0.5}\text{Al}_{1.5}$ ). A continuous series of solid solutions occur between the isotypic binary compounds ScRu and ScAl (ST CsCl) whereas a two-phase region exists between ScRu and RuAl (ST CsCl). In our opinion these data need additional verification if one takes into account the later data of Schuster and Bauer (1985) who observed the CrB structure type for pure ScAl (see sect. 2.12).

Karatygina et al. (1974b) reported the phase equilibria at 800°C in the region 0–85 at.% Al; later the same scientific group (Raevskaya and Sokolovskaya 1979) refined their earlier data. In addition to the earlier reported ternary compound, five other compounds were observed (see table 15). Of these, the crystal structure of  $\sim\text{ScRuAl}_2$  was determined to be of the  $\text{MnCu}_2\text{Al}$  type. Markiv and Storozhenko (1973) also synthesized a cubic ternary compound with a similar composition, namely  $\text{Sc}_6\text{Ru}_7\text{Al}_{16}$  crystallising in the  $\text{Mg}_6\text{Cu}_{16}\text{Si}_7$  structure type. To clarify these contradictory data additional work needs to be done. In our opinion, the data of Markiv and Storozhenko seem to be more reliable,

which is based on analysis of the data of related systems. Figures of the two isothermal sections mentioned above can be found in the review of Gladyshevsky et al. (1990).

### 3.2.17. *Sc-M-Al* ( $M = Rh, Os, Ir, Pt$ )

There is information in the literature about a ternary compound of the composition  $Sc_6M_7Al_{16}$  in each of the *Sc-M-Al* ( $M = Rh, Os, Ir$ ) ternary systems. Their lattice parameters are presented in table 15. Phase equilibria were not investigated. According to the investigation of Markiv and Storozhenko (1973) the compound of the 6:7:16 stoichiometry does not occur in the *Sc-Pt-Al* ternary system.

### 3.2.18. *Sc-Pd-Al*

Part of the *Sc-Pd-Al* isothermal section at 800°C shown in fig. 35 is based mainly on the data of Karatygina et al. (1974b). An extended solid solution is formed on the basis of the *ScPd* binary compound where the atoms of the initial components can substitute by each other in the structure. The binary compounds  $Sc_2Pd$  and  $Sc_4Pd$  dissolve about 13 and 8 at.% Al, whereas  $ScAl_2$  dissolves about 7 at.% Pd. Karatygina et al. synthesized three ternary compounds (see fig. 35); the existence of two other ternary compounds, namely  $Sc_6Pd_7Al_{16}$  and  $ScPd_2Al$  was reported by other authors (see table 15). The composition of the latter one occurs within the homogeneity range of the (Sc,Al)Pd solid solution observed by Karatygina et al. These conflicting data need additional refinement.

Fig. 35. *Sc-Pd-Al*, part of the isothermal section at 800°C (0–80 at.% Al). Ternary compounds: (1)  $\sim ScPd_{1.73}Al_{6.36}$ ; (2)  $\sim ScPdAl_3$ ; (3)  $ScPd_{0.30-0.57}Al_{1.70-1.43}$ .

Fig. 36. Sc-Cu-Al, part of the isothermal section at 500°C (0–33.3 at.% Sc). Ternary compounds: (1)  $\text{ScCu}_{4.0-6.15}\text{Al}_{8.0-5.85}$ ; (2)  $\sim\text{ScCu}_4\text{Al}_3$ ; (3)  $\text{Sc}_2\text{Cu}_{7.7}\text{Al}_{3.5}$ ; (4)  $\text{Sc}_3\text{Cu}_9\text{Al}_{17}$ ; (5)  $\text{Sc}_6\text{Cu}_{16.4}\text{Al}_{13.9}$ ; (6)  $\text{ScCu}_2\text{Al}_2$ ; (7)  $\text{ScCu}_2\text{Al}$ ; (8)  $\sim\text{ScCu}_{1.4}\text{Al}_{0.6}$ ; (9)  $\text{ScCuAl}$ ; (10)  $\text{ScCu}_{0.6}\text{Al}_{1.4}$ .

### 3.2.19. Sc-Cu-Al

Many investigations of the Sc-Cu-Al system have been reported. The phase equilibria in the range 0–33.3 at.% Sc at 500°C were first reported in the paper of Prevarskii et al. (1976). Nine ternary compounds were obtained: (1)  $\text{ScCu}_{4-6.6}\text{Al}_{8-5.4}$  (ST  $\text{ThMn}_{12}$ ,  $a = 8.66-8.63$ ,  $c = 4.43-5.10$  Å), (2)  $\sim\text{ScCu}_4\text{Al}_3$ , (3)  $\sim\text{ScCu}_{4.3}\text{Al}_{1.3}$ , (4)  $\sim\text{ScCu}_{2.6}\text{Al}_{2.3}$ , (5)  $\sim\text{ScCu}_3\text{Al}_2$ , (6)  $\sim\text{ScCu}_2\text{Al}_2$ , (7)  $\text{ScCu}_2\text{Al}$  (8)  $\sim\text{ScCu}_{1.4}\text{Al}_{0.6}$  and (9)  $\text{ScCuAl}$ . Two of them, (9)  $\text{ScCuAl}$  (ST  $\text{MgZn}_2$ ) and (7)  $\text{ScCu}_2\text{Al}$  (ST  $\text{CsCl}$ ), were synthesized earlier (Teslyuk and Protasov 1965b). Toropova et al. (1989) and Kharakterova (1991) reinvestigated the Al corner of the system at 450 and 500°C. They did not confirm the two phase equilibria between  $\text{CuAl}_2$  and  $\text{ScAl}_3$ , however they established the two phase equilibrium between Al and ternary compound (1). Kotur (1989) refined the homogeneity range and the lattice parameters of compound (1) (see table 15). Kharakterova determined the solubility of Sc and Cu in solid Al (about 1.5 at.% Cu and about 0.1 at.% Sc at 500°C). Gladyshevsky et al. (1992), who conducted a crystal structure investigation of four of the ternary compounds reported earlier by Prevarskii et al., refined their compositions to (3)  $\text{Sc}_2\text{Cu}_{7.5}\text{Al}_{3.5}$ , (4)  $\text{Sc}_3\text{Cu}_9\text{Al}_7$ , (5)  $\text{Sc}_6\text{Cu}_{16.4}\text{Al}_{13.9}$ , (6)  $\text{ScCu}_2\text{Al}_2$ , discovered an additional ternary compound (10)  $\text{ScCu}_{0.6}\text{Al}_{1.4}$ , and determined the crystal structures of all five compositions. These data are presented in table 15. The revised isothermal section at 500°C based on the above mentioned papers is shown in fig. 36. There is some controversy concerning the published data for the crystal structure of the  $\text{ScCu}_2\text{Al}$  compound. Teslyuk and Protasov (1965b) investigated an as-cast sample and a sample

homogenized at 800°C of the  $\text{ScCu}_2\text{Al}$  composition, and they obtained identical X-ray patterns for both samples. Between the two possible structure types ( $\text{MnCu}_2\text{Al}$  and  $\text{CsCl}$ ) they preferred the latter one ( $a=3.10 \text{ \AA}$ ), however, there were two weak extra lines which could be indexed assuming  $\text{MnCu}_2\text{Al}$  type. The  $\text{MnCu}_2\text{Al}$  structure for this phase was reported by Dwight and Kimball (1987). Recently Nakonechna and Shpyrka (1996) confirmed the  $\text{MnCu}_2\text{Al}$  type structure by single-crystal investigation (see table 15).

### 3.2.20. *Sc-M-Al* ( $M = \text{Ag}, \text{Au}$ )

Dwight and Kimball (1987) prepared the Heusler phases  $\text{ScAg}_2\text{Al}$  and  $\text{ScAu}_2\text{Al}$  and determined their lattice parameters (see table 15). Data about phase equilibria in these systems are not available in the literature.

## 3.3. *Sc-M-Ga ternary systems*

### 3.3.1. *Sc-Y-Ga*

Markiv et al. (1981) reported on the isothermal section of the  $\text{Sc-Y-Ga}$  system at 800°C in the range 0–75 at.% Sc (fig. 37). The gallides  $\text{ScGa}_2$  and  $\text{ScGa}_3$  dissolve about 9 at.% Y,  $\text{Sc}_3\text{Ga}_5$  (in the original paper “ $\text{Sc}_2\text{Ga}_3$ ”) dissolves about 36 at.% Y. One ternary compound with an extended homogeneity range along 44.5 at.% Ga isoconcentrate occurs in the system, however its crystal structure is unknown (table 16). Markiv et al. found the solubility of gallium in solid scandium at 800°C to be about 1 at.%. This value differs from those (between about 4 and 6 at.% Ga) reported in other papers on the  $\text{Sc-M-Ga}$

Fig. 37.  $\text{Sc-Y-Ga}$ , part of the isothermal section at 800°C (0–75 at.% Sc). Ternary compound:  
(1)  $\text{Sc}_{1.26-3.82}\text{Y}_{3.74-1.18}\text{Ga}_4$ .

system (see figs. 38–46). This is an additional reason for a reinvestigation of the Sc–Ga binary system which we mentioned in sect. 2.12. Complete miscibility between  $\text{Sc}_5\text{Ga}_3$  and  $\text{Y}_5\text{Ga}_3$  is observed (fig. 37).

### 3.3.2. Sc–Ti–Ga

The Sc–Ti–Ga isothermal section at  $800^\circ\text{C}$  (0–75 at.% Ga) has been investigated by Gavrilenko and Markiv (1978a); three ternary compounds were observed. Markiv et al. (1989) determined the solubility of titanium in  $\text{Sc}_5\text{Ga}_4$  (5 at.%) together with the composition and the crystal structure of another ternary compound, reported in the original paper as “ $\text{Sc}_{2-2.37}\text{TiGa}_{3-2.63}$ ” [compound (3) in the modified isothermal section presented in fig. 38]. The characteristic data of the ternary compounds are given in table 16.

Fig. 38. Sc–Ti–Ga, part of the isothermal section at  $800^\circ\text{C}$  (0–75 at.% Sc). Ternary compounds: (1)  $\text{Sc}_{1-4}\text{Ti}_{4-1}\text{Ga}_3$ ; (2)  $\text{ScTi}_2\text{Ga}_4$ ; (3)  $\text{Sc}_{6.8-9.4}\text{Ti}_{4.2-1.6}\text{Ga}_{10}$ .

### 3.3.3. Sc–Zr–Ga

The revised isothermal section of the Sc–Zr–Ga system at  $800^\circ\text{C}$  (0–75 at.% Ga) presented in fig. 39 is based mainly on the data of Markiv et al. (1979). They observed one ternary compound “ $\text{Sc}_{1.8-2.7}\text{Zr}_{3.2-2.3}\text{Ga}_4$ ”. Its composition and crystal structure, as well as the solubility of zirconium in  $\text{Sc}_5\text{Ga}_4$  (10 at.%), were determined by Markiv et al. (1989) (see table 16). The other binary gallides  $\text{Sc}_3\text{Ga}_5$ ,  $\text{Zr}_3\text{Ga}_2$  and  $\text{ZrGa}$  dissolve about 15 at.% Zr, about 12 and 46 at.% Sc, respectively (see fig. 39).  $\text{Zr}_5\text{Ga}_3$ – $\text{Sc}_5\text{Ga}_3$  form a continuous series of solid solutions between the two binary end members.

Fig. 39. Sc-Zr-Ga, part of the isothermal section at 800°C (0–75 at.% Sc). Ternary compound: (1)  $\text{Sc}_{3.2-4.7}\text{Zr}_{7.8-6.3}\text{Ga}_{10}$ .

### 3.3.4. Sc-Hf-Ga

Investigations of the Sc-Hf-Ga phase equilibria at 800°C in the range 0–63 at.% Ga have been reported by Belyavina et al. (1981), and by Markiv and Belyavina (1981) in the range 0–75 at.% Ga. The data of both papers are identical in the concentration range 0–50 at.% Ga.  $\text{Sc}_5\text{Ga}_4$  dissolves up to 15 at.% Hf. The hafnium gallide “ $\text{Hf}_5\text{Ga}_4$ ” dissolves up to 20 at.% Sc. Later the same scientific group (Markiv et al., 1989) refined the composition of this compound to  $\text{Hf}_{11}\text{Ga}_{10}$  and found its solubility of Sc to be 30 at.%. Other binary gallides, such as  $\text{Sc}_5\text{Ga}_3$  (in the original paper “ $\text{Sc}_2\text{Ga}_3$ ”) and  $\text{HfGa}_2$  also dissolve rather large amounts of the third component: 30 at.% Hf and 10 at.% Sc, respectively. Two ternary compounds have been synthesized by Markiv and Belyavina who also established their crystal structure (see table 16).  $\text{Sc}_5\text{Ga}_3$  and  $\text{Hf}_5\text{Ga}_3$  mutually dissolve 100% of each other. The revised isothermal section at 800°C is shown in fig. 40.

### 3.3.5. Sc-V-Ga

Savitskii et al. (1978b) studied the Sc-V-Ga phase equilibria at 800°C. The figure of the isothermal section is available in the review of Gladyshevsky et al. (1990). One ternary compound  $\text{ScV}_2\text{Ga}_4$  occurs in this system, its crystal structure was determined by Grin’ et al. (1980) (see table 16). The solubility of V in Sc(Ga) solid solution slightly increases with increase temperature, but it does not exceed 2 at.%. In as-cast alloys the solid solution based on vanadium spreads up to about 20 at.% Sc with increasing gallium content. The solubility of V in  $\text{Sc}_5\text{Ga}_3$  also increases with the increasing temperature and reaches about 10–12 at.% V.

Fig. 40. Sc-Hf-Ga, part of the isothermal section at 800°C (0–75 at.% Sc). Ternary compounds: (1)  $\text{Sc}_{0.2}\text{Hf}_{0.8}\text{Ga}_3$ ; (2)  $\text{Sc}_{0.2-0.9}\text{Hf}_{0.8-0.1}\text{Ga}$ .

### 3.3.6. Sc-Nb-Ga

During the investigation of the Sc-Nb-Ga alloys by Savitskii et al. (1980a) part of the phase equilibria at 800°C were established (0–75 at.% Sc) and two ternary compounds were observed (see fig. 41). One of the compounds,  $\sim\text{ScNbGa}_2$ , is formed after long-term homogenization of the alloys at 800°C. The composition of the second reported compound, “ $\text{Sc}_{3.8-4.2}\text{Nb}_{1.2-0.4}\text{Ga}_4$ ”, was refined to  $\text{Sc}_{8.4-9.4}\text{Nb}_{2.6-1.6}\text{Ga}_{10}$  by Markiv et al. (1989) who also determined its crystal structure (see table 16).

### 3.3.7. Sc-Cr-Ga

Gavrilenko and Markiv (1978a) investigated part of the Sc-Cr-Ga isothermal section at 800°C, and its figure is presented in the review of Gladyshevsky et al. (1990). One ternary compound  $\sim\text{Sc}_4\text{Cr}_2\text{Ga}_3$  occurs in this system, but its crystal structure is unknown (table 16).

### 3.3.8. Sc-Mn-Ga

Gavrilenko and Markiv (1978b) investigated part of the Sc-Mn-Ga isothermal section at 500°C (0–80 at.% Ga). Among the binary compounds of the Sc-Mn, Sc-Ga and Mn-Ga binary systems only  $\text{ScMn}_2$  (ST  $\text{MgZn}_2$ ) dissolves a large amount of the third component: up to 40 at.% Ga. The lattice parameters increase from  $a = 5.03$ ,  $c = 8.19$  (for  $\text{ScMn}_2$ ) to  $a = 5.22$ ,  $c = 8.52$  Å for  $\text{ScMn}_{0.8}\text{Ga}_{1.2}$ . Three ternary compounds were synthesized in the system and their compositions and the crystal structures were published in subsequent papers of the same scientific group: compound (1) “ $\text{Sc}_{25}\text{Mn}_{25}\text{Ga}_{50}$ ” by Markiv and Belyavina (1987b), compound (2) “ $\text{Sc}_{36}\text{Mn}_{10}\text{Ga}_{54}$ ” by Belyavina (1983), compound (3)

Fig. 41. Sc-Nb-Ga, part of the isothermal section at 800°C (0–75 at.% Sc). Ternary compounds: (1)  $\sim$ ScNbGa<sub>4</sub>; (2)  $\text{Sc}_{8.4-9.4}\text{Nb}_{2.6-1.6}\text{Ga}_{10}$ .

“ $\text{Sc}_{77}\text{Mn}_{13}\text{Ga}_{10}$ ” by Markiv and Belyavina (1989a). The refined compositions of these compounds are presented in a modified isothermal section, which is shown in fig. 42.

Fig. 42. Sc-Mn-Ga, part of the isothermal section at 500°C (0–80 at.% Sc). Ternary compounds: (1)  $\text{Sc}_3\text{Mn}_2\text{Ga}_6$ ; (2)  $\text{ScMn}_{0.33}\text{Ga}_{1.67}$ ; (3)  $\text{Sc}_{8.5}\text{Mn}_{1.2}\text{Ga}$ .

The characteristics of their crystal structures are summarised in table 16.

### 3.3.9. Sc-Fe-Ga

The Sc-Fe-Ga isothermal section at 800°C in the range 0–75 at.% Ga had been reported by Gavrilenko and Markiv (1978b). They established seven ternary compounds, for four of them a complete or partially investigated crystal structure was given. Belyavina and Markiv (1982a) reinvestigated the alloys of 7.7 at.% Sc isoconcentrate with the Ga content from 38 to 62 at.%. They did not confirm the data of Gavrilenko and Markiv about the crystal structure of “ $\text{ScFe}_{6.75-4.96}\text{Ga}_{5.25-7.04}$ ” at 800°C (ST  $\text{ThMn}_{12}$ ). A phase isotypic with  $\text{ThMn}_{12}$  was found to occur at 600°C in an alloy with the composition  $\text{ScFe}_{4.73}\text{Ga}_{7.27}$  (its lattice spacings are given in table 16). At 800°C an orthorhombic phase occurs closely related to  $\text{ThMn}_{12}$  type structure (see table 16). At 800°C a new compound, namely  $\text{Sc}_2\text{Fe}_{8.83}\text{Ga}_{8.17}$  was found; it is in equilibrium with the above-mentioned ternary phase and the  $\alpha(\text{Fe}, \text{Ga})$  solid solution. Kuzmenko et al. (1983) reported about another ternary compound:  $\text{ScFe}_{0.14}\text{Ga}_{1.86}$  (ST  $\text{CaIn}_2$ ) which was found in an as-cast alloy as well as in alloys annealed at 800°C. In other publications the compositions and the crystal structures of four other ternary compounds observed by Gavrilenko and Markiv were determined: (3) “ $\text{ScFe}_{1-0.8}\text{Ga}_{5-5.2}$ ” (Belyavina and Markiv 1980b), (7) “ $\text{Sc}_{36}\text{Fe}_9\text{Ga}_{55}$ ” (Kuzmenko et al., 1983), (4) “ $\text{Sc}_{28}\text{Fe}_{26.5-22.5}\text{Ga}_{45.4-49.4}$ ” (Markiv and Belyavina 1987b), (9) “ $\text{Sc}_{80}\text{Fe}_{12}\text{Ga}_8$ ” (Markiv and Belyavina 1989a). The modified isothermal section at 800°C based on these papers is presented in fig. 43. The composition of the “ $\text{Sc}_7\text{Fe}$ ”

Fig. 43. Sc-Fe-Ga, part of the isothermal section at 800°C (0–75 at.% Sc). Ternary compounds: (1)  $\text{ScFe}_{6-4.73}\text{Ga}_{6-7.27}$ ; (2)  $\text{ScFe}_{8.83}\text{Ga}_{8.17}$ ; (3)  $\text{ScFeGa}_5$ ; (4)  $\text{Sc}_3\text{Fe}_2\text{Ga}_6$ ; (5)  $\text{ScFe}_{1.82-1.44}\text{Ga}_{0.18-0.56}$ ; (6)  $\text{ScFe}_{1.37-0.71}\text{Ga}_{0.63-1.29}$ ; (7)  $\text{ScFe}_{0.33}\text{Ga}_{1.67}$ ; (8)  $\text{ScFe}_{0.14}\text{Ga}_{0.86}$ ; (9)  $\text{Sc}_{8.5}\text{Fe}_{1.2}\text{Ga}$ .

binary compound has been corrected in this figure too (see also sect. 2.8). The crystal structure characteristics of all observed Sc–Fe–Ga ternary compounds are presented in table 16.

### 3.3.10. Sc–Co–Ga

A number of papers dealing with investigations of Sc–Co–Ga alloys and compounds have been published. Figure 44 presents a revised isothermal section at 800°C. Gavrilenko and Markiv (1979) reported on the isothermal section at 800°C in the range 0–75 at.% Ga. Sc–Co binary compounds dissolve large quantities of Ga: from 8 at.% ( $\text{Sc}_3\text{Co}$ ) to 37 at.% ( $\text{ScCo}$ ). The solubility of Co in  $\text{Sc}_5\text{Ga}_3$  is about 11 at.%. Fifteen ternary compounds were reported to occur in the system at 800°C. Gavrilenko and Markiv confirmed the data of Markiv and Burnashova (1969) concerning  $\text{Sc}_6\text{Co}_7\text{Ga}_{16}$  and determined its homogeneity range at 800°C: (8)  $\text{Sc}_6\text{Co}_{7.2-6.3}\text{Ga}_{15.8-16.7}$ . They also established the crystal structure of the phase (12)  $\text{Sc}_{29-34}\text{Co}_{40-24}\text{Ga}_{29-42}$  (see table 16). In later publications of Markiv and co-workers data about the crystal structure and proper compositions of other nine ternary compounds are given: (4) “ $\text{ScCo}_{1-0.75}\text{Ga}_{4-4.25}$ ” and (7) “ $\text{Sc}_{19}\text{Co}_{12}\text{Ga}_{69}$ ” by Belyavina and Markiv (1980b), (1) “ $\text{Sc}_9\text{Co}_{45}\text{Ga}_{46}$ ” by Belyavina and Markiv (1982a), (13) “ $\text{ScCo}_{0.35-0.20}\text{Ga}_{1.65-1.80}$ ” by Belyavina and Markiv (1982b), (2) “ $\text{ScCo}_{3.96-3.72}\text{Ga}_{3.04-3.28}$ ”, (3) “ $\text{ScCo}_2\text{Ga}_5$ ” and (6) “ $\text{ScCo}_3\text{Ga}_2$ ” by Markiv and Belyavina (1987a), (15) “ $\text{Sc}_{74}\text{Co}_{13}\text{Ga}_{13}$ ” by Markiv and Belyavina (1989b), and

Fig. 44. Sc–Co–Ga, part of the isothermal section at 800°C (0–75 at.% Sc). Ternary compounds: (1)  $\text{ScCo}_{5.8}\text{Ga}_{6.2}$ ; (2)  $\text{ScCo}_{4.5}\text{Ga}_{4.1}$ ; (3)  $\text{Sc}_2\text{Co}_3\text{Ga}_9$ ; (4)  $\text{ScCoGa}_5$ ; (5)  $\sim\text{Sc}_{17}\text{Co}_{64-62}\text{Ga}_{19-21}$ ; (6)  $\text{Sc}_2\text{Co}_7\text{Ga}_4$ ; (7)  $\text{Sc}_2\text{CoGa}_8$ ; (8)  $\text{Sc}_6\text{Co}_{7.2-6.3}\text{Ga}_{15.8-16.7}$ ; (9)  $\sim\text{Sc}_{22}\text{Co}_{63-60}\text{Ga}_{15-18}$ ; (10)  $\sim\text{Sc}_{22}\text{Co}_{53-49}\text{Ga}_{25-29}$ ; (11)  $\text{ScCo}_{1.2}\text{Ga}_{1.8}$ ; (12)  $\text{Sc}_{29-34}\text{Co}_{48-24}\text{Ga}_{29-42}$ ; (13)  $\text{ScCo}_{0.35}\text{Ga}_{1.65}$ ; (14)  $\sim\text{Sc}_{37}\text{Co}_{14}\text{Ga}_{49}$ ; (15)  $\text{Sc}_5\text{Co}_{0.925}\text{Ga}_{0.925}$ .

(11) “ $\text{Sc}_{27}\text{Co}_{26}\text{Ga}_{47}$ ” by Belyavina and Markiv (1989). The refined compositions and the crystal structure data of these compounds are presented in fig. 44 and in table 16. The crystal structures of four Sc–Co–Ga ternary compounds are still unknown (see table 16). Kuzmenko et al. (1983) reinvestigated the alloys of the  $\text{ScCu}_2$ – $\text{ScGa}_2$  section and identified two other ternary compounds, namely  $\text{ScCo}_{0.14}\text{Ga}_{1.86}$  (ST  $\text{CaIn}_2$ ) and  $\text{ScCo}_{0.5}\text{Ga}_{1.5}$  (ST  $\text{KHg}_2$ ), which were observed only in the as-cast alloys (for their lattice spacings see table 16). The latter compound disintegrates into the ternary phases (12) and (13) during homogenization at 800°C.

### 3.3.11. Sc–Ni–Ga

Gavrilenko and Markiv (1979) presented data about the phase equilibria in the Sc–Ni–Ga system at 800°C in the range 0–75 at.% Ga. They synthesized fourteen ternary compounds, but for only three of them [ $\text{ScNi}_2\text{Ga}$  (ST  $\text{MnCu}_2\text{Al}$ ),  $\text{Sc}_{30-36}\text{Ni}_{55-39}\text{Ga}_{15-25}$  (ST  $\text{MgZn}_2$ ),  $\text{Sc}_{33-38}\text{Ni}_{35-18}\text{Ga}_{32-44}$  (ST  $\text{CaIn}_2$ )] has the crystal structure data been given. The compositions of the other eleven compounds were determined tentatively. For eight of them the crystal structure investigations were performed afterwards, this also led to a refinement of their compositions: (1) “ $\text{ScNi}_{1-0.85}\text{Ga}_{4-4.15}$ ” and (7) “ $\text{Sc}_{20}\text{Ni}_{12}\text{Ga}_{68}$ ” by Belyavina and Markiv (1980b), (12) “ $\text{ScNi}_{0.50,26}\text{Ga}_{1.5-1.74}$ ” by Belyavina and Markiv (1982b), (10)  $\text{ScNiGa}_2$  by Markiv and Belyavina (1983), (9) “ $\text{Sc}_{27}\text{Ni}_{26}\text{Ga}_{47}$ ” by Belyavina and Markiv (1989), (14) “ $\text{Sc}_{70-73}\text{Ni}_{20-12}\text{Ga}_{10-15}$ ” by Markiv and Belyavina (1989b), (3) “ $\text{Sc}_{17}\text{Ni}_{54-41}\text{Ga}_{29-42}$ ” by Markiv and Belyavina (1990a), and (2) “ $\text{ScNi}_{2.60}\text{Ga}_{4.03}$ ” by Markiv and Belyavina (1990b). The refined compositions, the structure data of these compounds and the compositions of three other ternary compounds with unknown structures are given in table 16. Figure 45 shows the corrected isothermal section at 800°C based on all these publications. The solubility of Ga in  $\text{ScNi}_5$ ,  $\text{Sc}_2\text{Ni}_7$ ,  $\text{ScNi}_2$  and  $\text{ScNi}$  is 11.5, 8.0, 12.2 and 30 at.%, respectively. Kuzmenko et al. (1983) reinvestigated the alloys of the  $\text{ScNi}_2$ – $\text{ScGa}_2$  section. They rejected the data of Gavrilenko and Markiv (1979) concerning the crystal structure of the  $\text{Sc}_{33-38}\text{Ni}_{35-18}\text{Ga}_{32-44}$  compound (ST  $\text{CaIn}_2$ ,  $a = 4.184$ – $4.240$ ,  $c = 6.387$ – $6.584$  Å). Kuzmenko et al. observed the ternary compound of  $\text{CaIn}_2$  type only in the as-cast alloy at the composition of  $\text{ScNi}_{0.14}\text{Ga}_{1.86}$  (see table 16). For a compound of composition  $\text{ScNi}_{1-0.67}\text{Ga}_{1-1.33}$  at 800°C they found a structure of  $\text{KHg}_2$  type. For the alloy of the equiatomic composition,  $\text{ScNiGa}$ , the ordered structure of the  $\text{TiNiSi}$  type was preferred by Kuzmenko et al. (see table 16). Earlier, Dwight (1968) reported about the  $\text{ScNiGa}$  compound crystallising in the  $\text{KHg}_2$  type structure; the lattice parameters reported by Dwight for that phase,  $a = 4.164$ ,  $b = 6.306$ ,  $c = 7.230$  Å are in good agreement with the parameters found by Kuzmenko et al. (see table 16). There are no further data in the paper of Kuzmenko et al. whether the  $\text{ScNi}_{1-0.67}\text{Ga}_{1-1.33}$  compound has variable content of scandium or not. For that reason we have drawn a broad homogeneity range for that compound (13) in fig. 45 according to the earlier data of Gavrilenko and Markiv (1979).

Fig. 45. Sc–Ni–Ga, part of the isothermal section at 800°C (0–75 at.% Sc). Ternary compounds: (1) ScNiGa<sub>5</sub>; (2) ScNi<sub>2.36</sub>Ga<sub>3.64</sub>; (3) Sc<sub>2</sub>Ni<sub>7–5.5</sub>Ga<sub>4–5.5</sub>; (4) ~Sc<sub>17</sub>Ni<sub>64–59</sub>Ga<sub>19–24</sub>; (5) ~Sc<sub>22</sub>Ni<sub>58</sub>Ga<sub>20</sub>; (6) ~Sc<sub>23</sub>Ni<sub>61</sub>Ga<sub>16</sub>; (7) Sc<sub>2</sub>NiGa<sub>8</sub>; (8) ScNi<sub>2</sub>Ga; (9) ScNi<sub>1.2</sub>Ga<sub>1.8</sub>; (10) ScNiGa<sub>2</sub>; (11) Sc<sub>30–36</sub>Ni<sub>55–39</sub>Ga<sub>15–25</sub>; (12) ScNi<sub>0.35</sub>Ga<sub>1.65</sub>; (13) Sc<sub>33–38</sub>Ni<sub>35–18</sub>Ga<sub>32–44</sub>; (14) Sc<sub>5</sub>Ni<sub>0.963</sub>Ga<sub>0.963</sub>.

### 3.3.12. Sc–M–Ga (*M* = Ru, Rh, Pd, Os, Ir, Pt)

No data are available about phase equilibria in the six Sc–M–Ge (*M* = Ru, Rh, Pd, Os, Ir, Pt) ternary systems. Only occasional alloys were examined in each of these systems. As a result, in the Sc–Pd–Ga system two ternary compounds were synthesized and structurally characterised: ScPd<sub>2</sub>Ga and ScPdGa (see table 16). In each of the remaining five systems one ternary compound was observed: their compositions are Sc<sub>6</sub>M<sub>7</sub>Ga<sub>16</sub> (*M* = Ru, Rh, Os, Ir) and ScPtGa. The crystal structure data are given in table 16. According to the data of Markiv and Storozhenko (1973) Sc<sub>6</sub>M<sub>7</sub>Ga<sub>16</sub> (*M* = Pd, Pt) ternary compounds do not occur in either the as-cast alloys or the alloys homogenised at 800°C.

### 3.3.13. Sc–Cu–Ga

Gavrilenko and Markiv (1979) investigated a part of the Sc–Cu–Ga isothermal section at 800°C (0–75 at.% Ga), however without showing a figure. The isothermal section shown in fig. 46 is mainly based on the figure presented by Gavrilenko (1982). Eight ternary compounds occur in the investigated part of the system. The crystal structure was determined for six of them (see table 16). The compositions of two of these compounds, (2) “Sc<sub>15</sub>Cu<sub>52</sub>Ga<sub>33</sub>” and (5) “Sc<sub>22</sub>Cu<sub>55</sub>Ga<sub>23</sub>”, were refined as part of the crystal structure investigations by Markiv and Belyavina (1990b, 1989a). The compound (1) ScCu<sub>5.49–4.85</sub>Ga<sub>6.51–7.15</sub> was observed by Gavrilenko and Markiv in the as-cast alloy and in a sample homogenised at 600°C. At 800°C the alloys of this concentration region of the

Fig. 46. Sc–Cu–Ga, part of the isothermal section at 800°C (0–75 at.% Sc). Ternary compounds: (1)  $\text{ScCu}_{5.49-4.85}\text{Ga}_{6.51-7.15}$  (at 600°C); (2)  $\text{ScCu}_{3.7}\text{Ga}_{2.3}$ ; (3)  $\sim\text{ScCu}_{3.6}\text{Ga}_{1.4}$ ; (4)  $\sim\text{ScCu}_{3.2}\text{Ga}_{1.6}$ ; (5)  $\text{Sc}_{14}\text{Cu}_{37}\text{Ga}_{14}$ ; (6)  $\text{ScCu}_2\text{Ga}$ ; (7)  $\text{ScCu}_{1.40-0.86}\text{Ga}_{0.60-1.14}$ ; (8)  $\text{ScCu}_{0.77-0.26}\text{Ga}_{1.23-1.74}$ .

system are in the liquid state. Gavrilenko and Markiv (1979) reported about one ternary compound in the  $\text{ScCu}_2$ – $\text{ScGa}_2$  section:  $\text{ScCu}_{1.4-0.26}\text{Ga}_{0.6-1.74}$  (ST  $\text{CaIn}_2$ ,  $a = 4.211$ – $4.248$ ,  $c = 6.459$ – $6.588$  Å). In a later paper Markiv et al. (1984) examined again the alloys of that section and reported the existence of two ternary phases within that composition region, namely (7)  $\text{ScCu}_{1.40-0.86}\text{Ga}_{0.60-1.14}$  (ST  $\text{KHg}_2$ ) and (8)  $\text{ScCu}_{0.77-0.26}\text{Ga}_{1.23-1.74}$  (ST  $\text{CaIn}_2$ ) (for their lattice parameters see table 16). Dwight (1968) also reported about the existence of a hexagonal compound  $\text{ScCu}_{0.5}\text{Ga}_{1.5}$  (ST  $\text{Ni}_2\text{In}$ ,  $a = 4.254$ ,  $c = 6.612$ ), with a composition within the homogeneity range of the hexagonal compound (8) observed by Markiv et al. (1984), however, the values of the lattice spacings of the Dwight phase are higher than those reported by Gavrilenko and Markiv (1979) and Markiv et al. (1984).

### 3.4. Sc–M–In ternary systems

#### 3.4.1. Sc–Ni–In

There are no data about the phase equilibria in the Sc–Ni–In system. Three ternary compounds  $\text{ScNi}_4\text{In}$ ,  $\text{ScNi}_2\text{In}$  and  $\text{Sc}_2\text{Ni}_2\text{In}$  have been synthesized and their crystal structure determined (see table 17).

#### 3.4.2. Sc–Pd–In

Savitskii et al. (1980b) investigated the polythermal PdIn–PdSc section of the Sc–Pd–In ternary system. They observed a complete miscibility between the isotopic binary

Table 17  
Intermetallic compounds in the Sc–M–In ternary systems

Compound	Structure type or symmetry	Lattice parameters		Reference
		<i>a</i> (Å)	<i>c</i> (Å)	
ScNi <sub>4</sub> In	MgCu <sub>4</sub> Sn	6.872		Zaremba et al. (1984)
ScNi <sub>2</sub> In	MnCu <sub>2</sub> Al	6.256		Zaremba et al. (1984)

<sup>a</sup> For the ScPd<sub>2</sub>In composition.

compounds PdIn and PdSc (ST CsCl). After a reinvestigation of the same section Urvachev et al. (1983) established the occurrence of one ternary compound with an extended homogeneity range: Sc<sub>0.76–1.44</sub>Pd<sub>2</sub>In<sub>1.24–0.56</sub>, which is formed as the result of an atomic ordering of the observed earlier Pd(In<sub>x</sub>Sc<sub>1–x</sub>) solid solution. Dwight and Kimball (1987) reported about a ScPd<sub>2</sub>In compound crystallizing in the MnCu<sub>2</sub>Al type structure (see table 17) which is, obviously, the ordered type for the compound observed by Urvachev et al. (1983).

### 3.4.3. Sc–Pt–In

Dwight and Kimball (1987) identified a ternary compound of MnCu<sub>2</sub>Al type structure in the Sc–Pt–In alloy with the ScPt<sub>2</sub>In composition, homogenized at 700°C (see table 17). No information is available about other compounds or alloys of this system.

### 3.4.4. Sc–M–In (*M* = Cu, Ag, Au)

The occurrence of a Heusler type ternary compound, ScM<sub>2</sub>In, in each of the three Sc–M–In (*M* = Cu, Ag, Au) ternary systems has been reported by Dwight and Kimball (1987). Their lattice spacings are given in table 17. The alloys were homogenized at 700°C. No phase equilibria in these systems were investigated.

## 3.5. Sc–M–C ternary systems

### 3.5.1. Sc–Th–C

Krupka et al. (1973) observed the occurrence of a solid solution of scandium in the cubic thorium carbide, Th<sub>2</sub>C<sub>3</sub> (ST Pu<sub>2</sub>C<sub>3</sub>). The lattice parameter changes within the homogeneity range of Th<sub>2–0.6</sub>Sc<sub>0–1.4</sub>C<sub>3</sub> from *a* = 8.556 to *a* = 8.563 Å, the value for Th<sub>1.4</sub>Sc<sub>0.6</sub>C<sub>3</sub> is *a* = 8.530 Å.

### 3.5.2. *Sc-Ti-C*

Nowotny and Auer-Welsbach (1961) synthesized the ternary compound  $\text{ScTi}_3\text{C}_4$  isotypic with NaCl ( $a=4.5 \text{ \AA}$ ). Velikanova et al. (1989) evaluated the hypothetical projection of the solidus surfaces of the phase diagram. A wide range of continuous solid solutions between the isotypic binary carbides  $\text{ScC}_{1-x}$  and  $\text{TiC}_{1-x}$  (ST NaCl) was predicted by them. It might be that the ternary phase observed by Nowotny and Auer-Welsbach is a part of this solid solution, and possibly not an individual ternary compound. Recently this prediction was confirmed experimentally by Ilyenko et al. (1996) who confirmed a complete mutual solubility of  $\text{ScC}_{1-x}$  and  $\text{TiC}_{1-x}$ . These authors reported also that the  $\text{ScC}_{1-x}$  phase is in equilibrium with all the phases of the solidus surface. However, the paper by Ilyenko et al. does not contain a figure of the phase equilibria.

### 3.5.3. *Sc-M-C (M=Zr, Hf, V, Nb, Ta)*

Hypothetical projections of the solidus surfaces of the Sc-M-C ( $M=\text{Zr, Hf, V, Nb, Ta}$ ) phase diagrams are proposed in a paper of Velikanova et al. (1989). A complete miscibility of the binary carbides  $\text{ScC}_{1-x}$  and  $\text{MC}_{1-x}$  ( $M=\text{Zr, Hf, V, Nb, Ta}$ ) crystallizing in the NaCl type structure, and the absence of ternary compounds in each of these ternary systems is predicted. However, these data need to be confirmed experimentally. Recently Ilyenko et al. (1996) reported the existence of continuous solid solutions between  $\text{ScC}_{1-x}$  and  $\text{MC}_{1-x}$  ( $M=\text{Zr, Hf}$ ), and accordingly these solid solutions are in equilibria with all the phases of the solidus surface. The same authors reported that the  $\text{VC}_{1-x}$  binary carbide dissolves at least 15 at.% Sc while the V solubility in  $\text{ScC}_{1-x}$  is at least 17 at.%. These data reject the earlier prediction of a complete miscibility of the NaCl-type binary carbides in the system Sc-V-C. However, no figures of the phase equilibria are presented in the brief communication of Ilyenko et al.

### 3.5.4. *Sc-Cr-C*

A hypothetical projection of the solidus surfaces of the Sc-Cr-C phase diagram has been proposed and experimentally confirmed in the range 0–30 at.% C by Velikanova et al. (1989) and Artyukh et al. (1989) (see fig. 47a). At high carbon content one ternary compound  $\text{Sc}_2\text{CrC}_3$  occurs in the system (Artyukh et al.). Its melting temperature does not exceed 1600°C. Pecharskaya et al. (1990) established its crystal structure (see table 18). A second ternary compound  $\text{ScCrC}_2$ , occurring in two very closely related modifications  $\beta$  (HT) and  $\alpha$  (LT), has been reported by Pöttgen et al. (1995) (see table 18). Recently Artyukh et al. (1997) presented the phase equilibria over the whole concentration region of the system. In the carbon-rich range  $\text{ScC}_{1-x}\text{-Cr}_3\text{C}_2$  all the phases are in equilibria with the ternary compound  $\text{Sc}_2\text{CrC}_3$ . Scandium and chromium binary carbides dissolve no more than 1 to 1.5 at.% of the third component. However, the  $\text{ScCrC}_2$  ternary compound was not mentioned. Thus, an additional investigation of the system in the >40 at.% C region is necessary.

Fig. 47. (a) Sc–Cr–C, and (b) Sc–Mo–C parts of the projections of solidus surfaces (a, 0–30 at.% C; b, 0–42 at.% C).

### 3.5.5. Sc–Mo–C

Velikanova et al. (1989) evaluated hypothetical projection of solidus surfaces of the Sc–Mo–C phase diagram and confirmed it, at least partially, by experiment in 0–42 at.% C concentration region (see fig. 47b). The forecasted and the experimental data are in good agreement. No ternary compounds were observed. In the diagram presented by Velikanova et al. it is shown that about 8 at.% Sc is soluble in Mo at 1200°C. These data are in disagreement with the prediction of Brewer and Lamoreaux (1980) and the experimentally determined Sc–M ( $M=5A, 6A$  element) binary phase diagrams (see sect. 2.6). The solubility of scandium in these elements is very low (<0.1 at.%). The diagram presented in fig. 47b has been modified by taking this into account.

### 3.5.6. Sc–M–C ( $M=W, Re, Tc$ )

Hypothetical projections of solidus surfaces of the Sc–M–C ( $M=W, Re, Tc$ ) phase diagrams have been proposed: Sc–W–C by Velikanova et al. (1989), Sc–Re–C by Velikanova et al. and by Eremenko et al. (1989a), and Sc–Tc–C by Eremenko et al. (1989b). However, all these results need an experimental verification. No ternary compounds were predicted. Pöttgen and Jeitschko (1992) synthesized a ternary carbide  $Sc_5Re_2C_7$  and investigated its crystal structure (see table 18); these data do not confirm the predictions mentioned above.

### 3.5.7. Sc-Fe-C

The isothermal section of the Sc-Fe-C system at 600°C has been investigated by Pecharskaya (1989). The phase diagram presented in fig. 48 is mainly based on these data. The data concerning the binary Sc-C system are not in agreement with the Sc-C phase diagram presented by Gordijchuk (1987) (see sect. 2.14). Two ternary compounds ScFeC<sub>2</sub> and Sc<sub>3</sub>FeC<sub>4</sub> occur in this system. Their crystal structures were studied earlier by Marusin et al. (1985) and Tsokol' et al. (1986a) (see table 18).

### 3.5.8. Sc-Co-C

The Sc-Co-C phase equilibria at 600°C have been established by Pecharskaya (1989) and are shown in fig. 49. The data about the existence at 600°C of Sc<sub>4</sub>C<sub>3</sub> binary carbide are not in agreement with the other literature sources (see sect. 2.14). Earlier the existence of three ternary compounds were reported in the system. Their compositions and the crystal structure data are given in table 18.

Fig. 48. Sc-Fe-C, isothermal section at 600°C. Ternary compounds: (1)  $\text{ScFeC}_2$ ; (2)  $\text{Sc}_3\text{FeC}_4$ .

Fig. 49. Sc-Co-C, isothermal section at 600°C. Ternary compounds: (1)  $\text{ScCo}_3\text{C}$ ; (2)  $\text{ScCoC}_2$ ; (3)  $\text{Sc}_3\text{CoC}_4$ .

3.5.9. *Sc-Ni-C*

Two ternary compounds  $\text{ScNiC}_2$  and  $\text{Sc}_3\text{NiC}_4$  were synthesized and their crystal structure determined (see table 18). Later, Pecharskaya (1989) presented isothermal section at  $600^\circ\text{C}$  (see fig. 50). However, the existence of a  $\text{Sc}_4\text{C}_3$  binary compound at  $600^\circ\text{C}$  does not agree with the Sc-C phase diagram published by Gordijchuk (1987) (see sect. 2.13); this discrepancy needs to be cleared-up by a new investigation.

Fig. 50. Sc-Ni-C, isothermal section at  $600^\circ\text{C}$ . Ternary compounds: (1)  $\text{ScNiC}_2$ ; (2)  $\text{Sc}_3\text{NiC}_4$ .

3.5.10. *Sc-M-C (M = Ru, Rh, Pd)*

Holleck (1977) investigated the phase equilibria of the Sc-M-C ( $M = \text{Ru, Rh, Pd}$ ) systems at  $1300^\circ\text{C}$  in the ranges 0–40 (for  $M = \text{Ru}$ ), 0–50 (for  $M = \text{Rh}$ ) and 0–25 (for  $M = \text{Pd}$ ) at.% Sc. The isothermal sections presented in fig. 51 are modified by taking into account the newest data concerning the Sc-M ( $M = \text{Ru, Rh, Pd}$ ) phase diagrams. The compositions and their homogeneity ranges of the binary compounds at  $1300^\circ\text{C}$  were corrected (see sect. 2.9). One ternary compound occurs in the Sc-Ru-C system (see table 18). In the Sc-Rh-C system the solid solution due to the inclusion of carbon atoms into the lattice of the  $\text{ScRh}_3$  compound (ST  $\text{AuCu}_3$ ) was observed:  $\text{ScRh}_3\text{C}_{0-0.75}$ . Its lattice parameter varies from  $a = 3.900$  up to  $a = 4.025$  Å. Possibly this solid solution may reach the  $\text{ScRh}_3\text{C}$  composition.

Fig. 51. (a) Sc-Ru-C, (b) Sc-Rh-C, and (c) Sc-Pd-C parts of the isothermal sections at 1300°C (a, 0-40; b, 0-50; c, 0-25 at.% Sc). Ternary compound: (1)  $\text{ScRu}_3\text{C}$ .

### 3.5.11. Sc-Ir-C

One ternary compound  $\text{ScIr}_3\text{C}_{1-x}$  of the perovskite type structure has been synthesized by Holleck (1977) (see table 18), however the proper carbon content is unknown because of the loss of some of the component during its preparation. The compound is in the two phase equilibria with  $\text{ScIr}_2$  and C.

### 3.6. *Sc–M–Si ternary systems*

#### 3.6.1. *Sc–Y–Si*

Kotroczo and McColm (1987) investigated the quasibinary section  $\text{Sc}_5\text{Si}_3\text{--Y}_5\text{Si}_3$  of the Sc–Y–Si ternary system and found a limited solid solutions  $\text{Y}_{5-x}\text{Sc}_x\text{Si}_3$  ( $0 \leq x \leq 0.75$ ) and  $\text{Sc}_{5-y}\text{Y}_y\text{Si}_3$  ( $0 \leq y \leq 1$ ) during an examination of as-cast alloys. Later Kotur and Mokra (1994) during an investigation of the isothermal section of the ternary system at  $800^\circ\text{C}$  observed a complete miscibility of these isotypic binary silicides (see fig. 52). Another continuous solid solution occurs between the isotypic monosilicides of scandium and yttrium. The highest yttrium silicide,  $\text{YSi}_2$ , dissolves 20 at.% Sc. One ternary compound with a variable composition occurs in this system (see table 19).

Fig. 52. Sc–Y–Si, isothermal section at  $800^\circ\text{C}$ . Ternary compound: (1)  $\text{Sc}_{0.95-0.52}\text{Y}_{0.05-0.48}\text{Si}_{1.67}$ .

#### 3.6.2. *Sc–La–Si*

There are two ternary compounds known in the Sc–La–Si system:  $\text{ScLaSi}$  (Mokra and Bodak 1979) and  $\sim\text{ScLa}_2\text{Si}_2$  (Mokra 1979), however, the lattice parameters have been reported only for the first compound (see table 19).

#### 3.6.3. *Sc–Ce–Si*

An isothermal section of the Sc–Ce–Si phase diagram at  $600^\circ\text{C}$  has been investigated by Mokra (1979) and Bodak et al. (1981). Its figure was presented in the review of Rogl (1984b). Binary silicides of cerium and scandium do not dissolve more than 5 at.% of Sc and Ce respectively. All eight ternary compounds known in this system have variable

content of Ce and Sc within 2 to 4 at.%. These results were partially confirmed by Kotur et al. (1989c) who reported slightly different values for the lattice spacings for two of the ternary compounds,  $\text{ScCe}_2\text{Si}_2$  and  $\text{ScCeSi}$  (see table 19). The crystal structures of five ternary compounds are still unknown.

#### 3.6.4. *Sc-Pr-Si*

Banakh and Kotur (1997) reported about the Sc-Pr-Si isothermal section at 600°C. However, a figure of the section was not presented in that short communication. Eight ternary compounds occur in the system. Two of them,  $\text{ScPrSi}$  and  $\sim\text{ScPr}_2\text{Si}_2$ , had been synthesized earlier by Mokra and Bodak (1979) and Mokra (1979). The crystal structure has been determined for five of these compounds (see table 19).

#### 3.6.5. *Sc-Nd-Si*

Figure 53 shows the isothermal section of the Sc-Nd-Si system at 600°C which was determined by Banakh and Kotur (1998). The binary silicides  $\text{NdSi}_{2-x}$  and  $\text{NdSi}$  dissolve 15 and 7 at.% Sc, respectively. The solubility of the third component in other neodymium and scandium binary silicides does not exceed 2 at.%. Five ternary compounds exist in this system (see table 19). One of them, (4) in fig. 53, has variable composition of Sc and Nd. Four other have practically constant composition.

Fig. 53. Sc-Nd-Si, isothermal section at 600°C. Ternary compounds: (1)  $\sim\text{ScNd}_4\text{Si}_3$ ; (2)  $\text{ScNd}_2\text{Si}_2$ ; (3)  $\text{ScNdSi}$ ; (4)  $\text{Sc}_{0.85-0.95}\text{Nd}_{0.15-0.05}\text{Si}_{1.67}$ ; (5)  $\text{Sc}_4\text{NdSi}_4$ .

Fig. 54. Sc–Sm–Si, part of the isothermal section at 600°C (0–80 at.% Sc). Ternary compounds: (1)  $\text{Sc}_{0.3}\text{Sm}_{0.7}\text{Si}_2$ ; (2)  $\text{Sc}_{0.2-0.4}\text{Sm}_{0.8-0.6}\text{Si}$ ; (3)  $\text{ScSm}_2\text{Si}_2$ ; (4)  $\text{ScSmSi}$ ; (5)  $\text{Sc}_3\text{Sm}_2\text{Si}_4$ .

### 3.6.6. Sc–Sm–Si

Kotur et al. (1991) reported on part of the Sc–Sm–Si isothermal section at 600°C which is shown in fig. 54. All the samarium and scandium binary silicides dissolve different amounts of the third component, from 2 at.% Sm (ScSi compound) up to 13 at.% Sc ( $\text{Sm}_5\text{Si}_3$  compound). Five ternary compounds exist in the system, and the crystal structure is known for all of them (see table 19).

### 3.6.7. Sc–Dy–Si

The Sc–Dy–Si phase equilibria at 600°C have been investigated by Kotur et al. (1991) (fig. 55). Solid solutions of substitution of Sc and Dy of different extent on the basis of binary silicides occur in the system. DySi dissolve only 1 at.% Sc while the isotypic silicides  $\text{Sc}_5\text{Si}_3$  and  $\text{Dy}_5\text{Si}_3$  are completely miscible. The variations of the lattice spacings vs. composition of solid solutions obey Vegard's rule in case of  $\text{Sc}_{1-x}\text{Dy}_x\text{Si}$ , or show slight deviations from this rule ( $\text{Dy}_{5-x}\text{Sc}_x\text{Si}_3$ ,  $\text{Dy}_{5-x}\text{Sc}_x\text{Si}_4$ ). Two ternary compounds occur in this system (see table 19). One of them also has a variable composition of Sc and Dy.

### 3.6.8. Sc–Er–Si

Kotur and Parasiuk (1994) investigated the Sc–Er–Si isothermal section at 600°C which is depicted in fig. 56. Ternary compounds do not exist in this system. Pairs of isotypic binary silicides, namely ScSi and ErSi,  $\text{Sc}_5\text{Si}_3$  and  $\text{Er}_5\text{Si}_3$ , form continuous series of solid solutions.  $\text{ErSi}_{1.67}$  dissolves 32 at.% Sc.

Fig. 55. Sc–Dy–Si, isothermal section at 600°C. Ternary compounds: (1)  $Sc_{0.3}Dy_{0.7}Si_2$ ; (2)  $Sc_{0.4-0.7}Dy_{0.6-0.3}Si_{1.67}$ .

Fig. 56. Sc–Er–Si, isothermal section at 600°C.

3.6.9. Sc–Lu–Si

The Sc–Lu–Si isothermal section at 800°C, published by Kotur and Mokra (1994) (see fig. 57), is similar to that of the Sc–Er–Si system.  $LuSi_{2-x}$  dissolves 35 at.% Sc.

Fig. 57. Sc-Lu-Si, isothermal section at 800°C.

### 3.6.10. Sc-Ti-Si, Sc-Zr-Si

Parts of the isothermal sections of the Sc-Ti-Si and Sc-Zr-Si systems at 800°C were investigated by Kotur et al. (1989b) and are displayed in fig. 58. The phase equilibria are quite similar in both systems; no ternary compounds were observed. The binary silicides TiSi, TiSi<sub>2</sub>, ZrSi and ZrSi<sub>2</sub> dissolve 12, 10, 22 and 11 at.% Sc, respectively. Scandium monosilicide dissolves 9 at.% Ti or 15 at.% Zr.

Fig. 58. (a) Sc-Ti-Si, and (b) Sc-Zr-Si parts of the isothermal sections at 800°C (50–100 at.% Si).

Fig. 59. Sc-Hf-Si, isothermal section at 800°C.

### 3.6.11. Sc-Hf-Si

Kotur et al. (1989b) reported on a part of the Sc-Hf-Si isothermal section at 800°C (50–100 at.% Si). Later Kotur and Ratush (1991) investigated the isothermal section over the whole concentration region (see fig. 59). No ternary compounds exist in this system. The hafnium silicides  $\text{Hf}_2\text{Si}$ ,  $\text{Hf}_3\text{Si}_2$ ,  $\text{Hf}_5\text{Si}_4$ ,  $\text{HfSi}$  and  $\text{HfSi}_2$  dissolve 25, 10, 33, 10 and 24 at.% Sc, respectively.  $\text{ScSi}$  dissolves 33 at.% Hf. Continuous series of solid solutions occur between the isotypic silicides  $\text{Hf}_5\text{Si}_3$  and  $\text{Sc}_5\text{Si}_3$ . The variations of the lattice spacings of these solid solutions were measured by Kotur and Ratush.

### 3.6.12. Sc-V-Si

Kotur et al. (1983a) investigated alloys of the section  $\text{Sc}_5\text{Si}_3$ - $\text{V}_5\text{Si}_3$ , and later Kotur (1987) published the phase equilibria at 800°C for the whole concentration range (fig. 60). Three ternary compounds were synthesized and their crystal structures determined (see table 19). One of the compounds, namely  $\text{ScV}_5\text{Si}_5$ , has variable content of Sc and V within 2 at.%.

### 3.6.13. Sc-Nb-Si

The Sc-Nb-Si isothermal section at 800°C presented in fig. 61 has been reported by Kotur (1986). Solid solution of substitution  $\text{Sc}_{5-1.5}\text{Nb}_{0-3.5}\text{Si}_3$  occurs in the system. The variation of the lattice parameters show negative deviation from Vegard's rule. Other binary scandium and niobium silicides do not dissolve the third component. Two ternary compounds exist in the system. Probably  $\text{Sc}_{0.4}\text{Nb}_{4.6}\text{Si}_3$  is a solid solution of the binary

Fig. 60. Sc-V-Si, isothermal section at 800°C. Ternary compounds: (1)  $\text{ScV}_3\text{Si}_5$ ; (2)  $\text{Sc}_2\text{V}_3\text{Si}_4$ ; (3)  $\text{Sc}_2\text{V}_3\text{Si}_3$ .

$\beta\text{Nb}_5\text{Si}_3$  compound (which occurs in the Nb-Si system in the temperature range 2480–2000°C) stabilized by scandium.

Fig. 62. Sc-Ta-Si, isothermal section at 800°C.

#### 3.6.14. Sc-Ta-Si

Figure 62 displays the isothermal section of the Sc-Ta-Si system at 800°C reported by Kotur and Bodak (1990). Binary tantalum and scandium silicides (except  $\text{Sc}_5\text{Si}_3$ ) practically do not dissolve the third component.  $\text{Sc}_5\text{Si}_3$  dissolves less than 2 at.% Ta. No ternary compounds were observed.

#### 3.6.15. Sc-Cr-Si

Kotur and Bodak (1987) investigated the Sc-Cr-Si isothermal section at 800°C (see fig. 63). The scandium silicide  $\text{Sc}_5\text{Si}_3$  dissolves up to 2 at.% Cr. Three ternary compounds were synthesized and their crystal structures determined, the data are given in table 19.

#### 3.6.16. Sc-Mo-Si

The Sc-Mo-Si isothermal section at 800°C, which is based on the data of Kotur and Bodak (1988), is displayed in fig. 64. Only one binary compound, namely  $\text{Sc}_5\text{Si}_3$ , dissolves the third component: 25 at.% Mo. The lattice spacings change linearly within the homogeneity range of the solid solution. One ternary compound exists in this system, its crystal structure data are given in table 19.

#### 3.6.17. Sc-W-Si

The phase equilibria of the Sc-W-Si system at 800°C presented in fig. 65 are similar to those of Sc-Mo-Si system (Kotur et al., 1989a). The solubility of W in  $\text{Sc}_5\text{Si}_3$  is about

Fig. 63. Sc-Cr-Si, isothermal section at 800°C. Ternary compounds: (1)  $\text{ScCr}_4\text{Si}_5$ ; (2)  $\text{Sc}_2\text{Cr}_3\text{Si}_4$ ; (3)  $\text{Sc}_7\text{Cr}_{4.8}\text{Si}_{9.2}$ .

Fig. 64. Sc-Mo-Si, isothermal section at 800°C. Ternary compound: (1)  $\text{Sc}_2\text{Mo}_3\text{Si}_4$ .

4 at.%. The single ternary compound has variable content of Sc and W; it is isotypic with  $\text{Sm}_5\text{Ge}_4$  (table 19).

Fig. 65. Sc–W–Si, isothermal section at 800°C. Ternary compound: (1)  $\text{Sc}_{2-3}\text{W}_{3-2}\text{Si}_4$ .

### 3.6.18. Sc–Mn–Si

Kotur et al. (1977b, 1980) reported on a part of the Sc–Mn–Si isothermal section at 800°C. A figure of this section is available in the review of Rogl (1984b). Among the binary compounds only  $\text{ScMn}_2$  dissolves up to 20 at.% Si; the lattice parameters of this solid solution obey Vegard's rule within the homogeneity range. Four ternary compounds of constant compositions occur in this system, the crystal structures of all of them are known (see table 19).

### 3.6.19. Sc–Re–Si

Pecharsky (1979) and Bodak et al. (1981) each reported about parts of the phase equilibria of the Sc–Re–Si system at 800°C namely in the ranges 0–66.7 at.% Sc and 0–33.3 at.% Sc, respectively.  $\text{ScRe}_2$  dissolves about 21 at.% Si. The lattice parameters of the solid solution decrease linearly (from  $a=5.28$ ,  $c=8.58$  to  $a=5.17$ ,  $c=8.39$  Å) within the homogeneity range. Five ternary compounds were synthesized and the crystal structures of three of them:  $\text{Sc}_2\text{Re}_3\text{Si}_4$ ,  $\text{ScRe}_2\text{Si}_3$  and  $\text{Sc}_3\text{Re}_2\text{Si}_3$  were determined by Pecharsky et al. (1978, 1979). The structures of the two other  $\text{ScReSi}_2$  and  $\sim\text{Sc}_8\text{Re}_3\text{Si}_9$  were not reported. The single crystal investigation of Chabot and Parthé (1985) did not confirm the existence of compound “ $\text{Sc}_3\text{Re}_2\text{Si}_3$ ” at 800°C, it revealed a composition of  $\text{Sc}_3\text{Re}_2\text{Si}_4$ . As a result of precised single crystal investigations the compositions and crystal structures of two other compounds were refined: “ $\text{ScRe}_2\text{Si}_3$ ” to  $\text{Sc}_5\text{Re}_8\text{Si}_{12}$  (Chabot and Parthé, 1987) and “ $\text{Sc}_8\text{Re}_3\text{Si}_9$ ” to  $\text{Sc}_7\text{Re}_{3.35}\text{Si}_{10.65}$  (Zhao et al., 1988). The crystal structure data of these compounds are presented in table 19. A modified isothermal section at 800°C with the

Fig. 66. Sc–Re–Si, part of the isothermal section at 800°C (0–66.7 at.% Sc). Ternary compounds: (1)  $\text{Sc}_5\text{Re}_8\text{Si}_{12}$ ; (2)  $\text{Sc}_2\text{Re}_3\text{Si}_4$ ; (3)  $\sim\text{ScReSi}_2$ ; (4)  $\text{Sc}_3\text{Re}_2\text{Si}_4$ ; (5)  $\text{Sc}_7\text{Re}_{3.35}\text{Si}_{10.65}$ .

corrected compositions of the ternary compounds and corrections concerning the binary Re–Si system (according to the data of Massalski 1990) is shown in fig. 66.

### 3.6.20. Sc–Fe–Si

The isothermal section at 800°C presented in fig. 67 has been investigated by Gladyshevsky et al. (1977). Fourteen ternary compounds occur at that temperature in the system. Twelve of them have a constant composition. The composition of three compounds were refined afterwards: “ $\text{Sc}_3\text{Fe}_2\text{Si}_6$ ” to  $\text{ScFeSi}_2(\text{II})$  (Yarmolyuk et al., 1980), “ $\text{Sc}_3\text{Fe}_3\text{Si}_4$ ” to  $\text{Sc}_4\text{Fe}_4\text{Si}_7$  (Chabot et al. (1984) and Kotur (1983) independently), and “ $\text{ScFe}_3\text{Si}_6$ ” to  $\text{Sc}_{1.2}\text{Fe}_4\text{Si}_{9.8}$  (Kotur and Bruvo 1991). It is interesting to mention the existence of the ternary compound  $\text{ScFeSi}_2(\text{I})$ , which is in two-phase equilibria at 800°C with the ternary compounds  $\text{ScFeSi}_2(\text{II})$ ,  $\text{Sc}_2\text{Fe}_3\text{Si}_5$  and  $\text{Sc}_4\text{Fe}_4\text{Si}_7$ . Possibly the composition of the silicide  $\text{ScFeSi}_2(\text{I})$  is slightly shifted from the ideal stoichiometry; additional investigations are necessary to clarify this. Chabot et al. (1984) also found two other ternary compounds  $\text{Sc}_3\text{Fe}_2\text{Si}_3$  and  $\text{ScFeSi}$  in the as-cast alloys and confirmed the results published by Kotur and Sikirica (1983) concerning the  $\text{Sc}_2\text{FeSi}_2$  compound. The phase equilibria presented in fig. 67 include all the corrections mentioned above. The crystal structure data of the ternary compounds are summarized in table 19. A recently performed X-ray structure analysis of compound 12 in fig. 67 conducted by Kotur et al. (1998) revealed that this compound does not crystallize in a superstructure of the  $\text{Mg}_2\text{Cu}_3\text{Si}$ -type as reported earlier by Gladyshevsky et al. (1977) and Kotur (1977b), but shows a random distribution

Fig. 67. Sc-Fe-Si, isothermal section at 800°C. Ternary compounds: (1)  $\text{Sc}_{0.35}\text{Fe}_{4.65}\text{Si}_3$ ; (2)  $\text{ScFe}_{10}\text{Si}_2$ ; (3)  $\text{Sc}_{1.2}\text{Fe}_4\text{Si}_{3.8}$ ; (4)  $\sim\text{ScFe}_3\text{Si}_3$ ; (5)  $\text{ScFe}_4\text{Si}_2$ ; (6)  $\text{ScFe}_2\text{Si}_2$ ; (7)  $\text{Sc}_2\text{Fe}_3\text{Si}_5$ ; (8)  $\text{ScFeSi}_2(\text{I})$ ; (9)  $\text{ScFeSi}_2(\text{II})$ ; (10)  $\text{Sc}_4\text{Fe}_4\text{Si}_7$ ; (11)  $\text{Sc}_{1-1.09}\text{Fe}_{1.97-1.82}\text{Si}_{0.06-0.12}$ ; (12)  $\text{ScFe}_{1.5-1.42}\text{Si}_{0.5-0.58}$ ; (13)  $\text{ScFe}_{0.25}\text{Si}_{1.75}$ ; (14)  $\text{Sc}_2\text{FeSi}_2$ ; (15)  $\text{ScFeSi}$ ; (16)  $\text{Sc}_3\text{Fe}_2\text{Si}_3$ .

of Fe and Si atoms on the two crystallographic sites in the  $\text{MgZn}_2$ -type structure. For that reason the composition is  $\text{ScFe}_{1.5}\text{Si}_{0.5}$ , and not  $\text{Sc}_2\text{Fe}_3\text{Si}$  as in the earlier publications.

### 3.6.21. Sc-Co-Si

Figure 68 presents the Sc-Co-Si isothermal section at 800°C (and a part of it at 700°C) investigated by Kotur et al. (1977a).  $\text{ScCo}_2$  dissolves 6 at.% Si. The lattice parameter  $a$  of this solid solution increases linearly from 6.911 to 6.920 Å within the alloys on the isoconcentrate of 33.3 at.% Sc (Kotur 1977a). Kotur et al. confirmed the occurrence of two ternary compounds  $\text{ScCo}_2\text{Si}_2$  and  $\text{Sc}_6\text{Co}_{16}\text{Si}_7$  and synthesized ten new ternary silicides (see table 19). In the later papers the compositions of two ternary compounds have been refined: “ $\text{ScCo}_7\text{Si}_4$ ” to  $\text{Sc}_6\text{Co}_{30}\text{Si}_{19}$  (Kotur and Sikirica 1991), and “ $\text{Sc}_3\text{Co}_2\text{Si}_5$ ” to  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$  (Braun et al. 1980). The phase equilibria shown in fig. 68 include all these refinements. Kotur et al. (1998) corrected the crystal structure of compound 7 in fig. 68 to the  $\text{MgZn}_2$ -type instead of the superstructure  $\text{Mg}_2\text{Cu}_3\text{Si}$ -type as reported earlier (see Kotur 1977b). The compound  $\text{Sc}_2\text{Co}_{0.85}\text{Si}_{0.15}$  exists only in alloys annealed at 800°C; perhaps it is formed by a solid-state phase reaction.

### 3.6.22. Sc-Ni-Si

In a systematic investigation of the Sc-Ni-Si phase equilibria at 800°C in the range 0–70 at.% Sc performed by Bodak et al. (1976) fifteen ternary compounds have been

Fig. 68. Sc–Co–Si, part of the isothermal sections at 800°C and at 700°C (0–70 at.% Sc). Ternary compounds: (1)  $\text{Sc}_6\text{Co}_{30}\text{Si}_{19}$ ; (2)  $\sim\text{Sc}_4\text{Co}_{14}\text{Si}_5$ ; (3)  $\text{Sc}_6\text{Co}_{16}\text{Si}_7$ ; (4)  $\text{ScCo}_2\text{Si}_2$ ; (5)  $\text{Sc}_2\text{Co}_3\text{Si}_3$ ; (6)  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ ; (7)  $\text{ScCo}_{1.52-1.46}\text{Si}_{0.48-0.54}$ ; (8)  $\text{ScCoSi}$ ; (9)  $\text{ScCo}_{0.25}\text{Si}_{1.75}$ ; (10)  $\text{Sc}_3\text{Co}_2\text{Si}_3$ ; (11)  $\text{Sc}_2\text{CoSi}_2$ ; (12)  $\text{Sc}_2\text{Co}_{0.85}\text{Si}_{0.15}$ .

synthesized (fig. 69); two of these ternary compounds, namely  $\text{ScNi}_2\text{Si}_2$  and  $\text{Sc}_6\text{Ni}_{16}\text{Si}_7$  had been known earlier (see table 19). Further investigations revealed a change of the compositions of six ternary compounds observed by Bodak et al.: (2) “ $\text{Sc}_{15}\text{Ni}_{62.5}\text{Si}_{22.5}$ ” (Kotur et al. 1983b), (3) “ $\text{Sc}_{17.5}\text{Ni}_{30}\text{Si}_{52.5}$ ” (Kotur et al. 1978), (4) “ $\text{Sc}_{15}\text{Ni}_{50}\text{Si}_{35}$ ” (Kotur et al. 1986d), (12) “ $\text{Sc}_{35}\text{Ni}_{20}\text{Si}_{45}$ ” (Zhao and Parthé 1989a,b), (13) “ $\text{Sc}_{32}\text{Ni}_8\text{Si}_{60}$ ” (Kotur and Bodak 1977), (15) “ $\text{Sc}_{44}\text{Ni}_{12}\text{Si}_{44}$ ” (Kotur and Gladyshevsky 1983). Their crystal structure data can be found in table 19. The phase equilibria at 800°C are presented in fig. 69 assuming these refinements. The binary  $\text{ScNi}_2$  compound dissolves a large amount of the third component: about 7 at.% Si. The lattice spacing of the solid solution increases linearly from  $a = 6.901$  to  $6.909 \text{ \AA}$  (Kotur 1977a). Other Sc–Ni binary compounds dissolve less than 2 to 3 at.% Si.

### 3.6.23. Sc–Ru–Si

No data are known about the phase equilibria occurring in the Sc–Ru–Si system. Only two ternary compounds have been synthesized and their crystal structures investigated (see table 19).

### 3.6.24. Sc–Rh–Si

Braun et al. (1979) investigated a part of the Sc–Rh–Si isothermal section at 1000°C (44–100 at.% Si); the figure can be found in Rogl (1984b). Nine ternary compounds

Fig. 69. Sc–Ni–Si, part of the isothermal section at 800°C (0–70 at.% Sc). Ternary compounds: (1)  $\sim\text{Sc}_2\text{Ni}_9\text{Si}_9$ ; (2)  $\text{Sc}_3\text{Ni}_{11}\text{Si}_4$ ; (3)  $\text{ScNi}_2\text{Si}_3$ ; (4)  $\text{Sc}_6\text{Ni}_{18}\text{Si}_{11}$ ; (5)  $\text{Sc}_6\text{Ni}_{16}\text{Si}_7$ ; (6)  $\sim\text{Sc}_2\text{Ni}_5\text{Si}_3$ ; (7)  $\text{ScNi}_2\text{Si}_2$ ; (8)  $\text{ScNiSi}_3$ ; (9)  $\text{Sc}_3\text{Ni}_4\text{Si}_4$ ; (10)  $\text{ScNi}_{1.52-1.49}\text{Si}_{0.48-0.51}$ ; (11)  $\text{ScNiSi}$ ; (12)  $\text{Sc}_3\text{Ni}_2\text{Si}_4$ ; (13)  $\text{ScNi}_{0.25}\text{Si}_{1.75}$ ; (14)  $\text{Sc}_3\text{Ni}_2\text{Si}_3$ ; (15)  $\text{Sc}_3\text{NiSi}_3$ .

were observed. Hovestreydt et al. (1982) reported about the existence of another one,  $\text{ScRhSi}$ . Chabot et al. (1981b) refined the composition of the “ $\text{ScRh}_3\text{Si}_6$ ” compound to  $\text{ScRh}_3\text{Si}_7$  and determined its crystal structure. But the proper compositions and the crystal structures of six other ternary compounds remain still unknown (see table 19). Braun et al. also investigated a part of the phase equilibria at 800 and 1150°C. These investigations revealed that  $\text{ScRh}_3\text{Si}_2$  is not in equilibrium with Si at 1150°C, and the ternary compound  $\text{Sc}_3\text{Rh}_4\text{Si}_{10}$  does not exist at 800°C; furthermore it is shown that the silicides  $\text{Sc}_4\text{RhSi}_8$  and  $\text{ScRhSi}_2$  are in equilibrium.

### 3.6.25. Sc–Pd(Os, Ir, Pt)–Si

There are no literature data about the phase equilibria of the Sc–Pd(Os, Ir, Pt)–Si systems. Only one ternary compound within each system (except Sc–Ir–Si) were observed by the examination of separate alloys for isotypic compounds existing in related ternary systems. In the Sc–Ir–Si system four ternary compounds were obtained. Their compositions and the crystal structure data are collected in table 19.

### 3.6.26. Sc–Cu–Si

According to the investigation of Kotur et al. (1985b) there are insignificant differences in the phase equilibria at 600 and 800°C of the Sc–Cu–Si system (see fig. 70). Five ternary compounds occur in the system. Two of them,  $\text{Sc}_3\text{Cu}_4\text{Si}_4$  and  $\text{ScCuSi(h)}$ , had been known

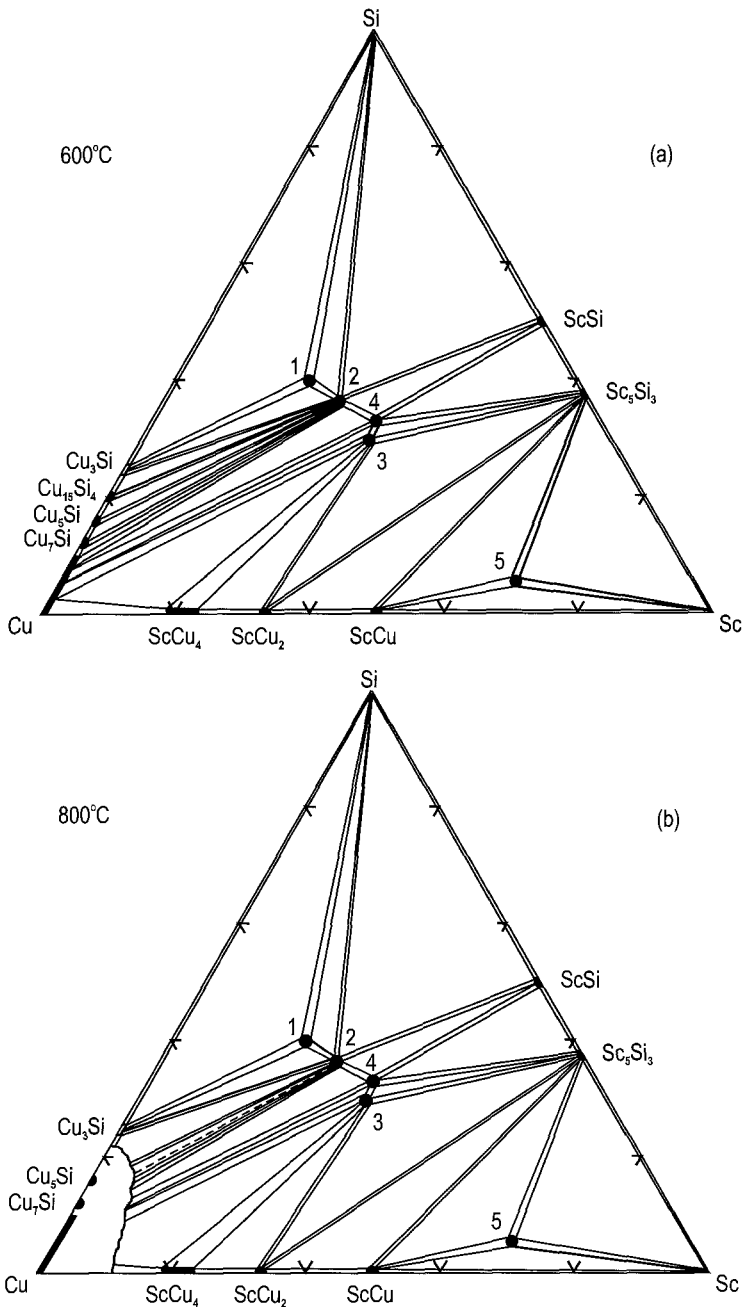

Fig. 70. Sc-Cu-Si, isothermal sections at (a) 600°C and (b) 800°C. Ternary compounds: (1) ScCu<sub>2</sub>Si<sub>2</sub>; (2) Sc<sub>3</sub>Cu<sub>4</sub>Si<sub>4</sub>; (3) ScCuSi(h); (4) ScCuSi(r); (5) Sc<sub>2</sub>Cu<sub>0.8</sub>Si<sub>0.2</sub>.

earlier. The crystal structures are established for all compounds (see table 19). Two ternary phases  $\text{ScCuSi(h)}$  and  $\text{Sc}_2\text{Cu}_{0.8}\text{Si}_{0.2}$  appear only after a long-term homogenization of alloys, whereas three other ternary silicides were observed also in the as-cast alloys. Two ternary compounds with compositions close to equiatomic coexist in the system (Kotur et al. 1981). They are separated by a narrow two-phase region, thus a detailed investigation is necessary to find out their proper compositions.

### 3.6.27. *Sc–Ag–Si*

No ternary compound was observed by Kotur and Boichuk (1988) in the *Sc–Ag–Si* isothermal section at  $600^\circ\text{C}$ , which is shown in fig. 71. These results agree with those of Iandelli (1985), who investigated the alloy of equiatomic composition and established the existence of two phases.

Fig. 71. *Sc–Ag–Si*, isothermal section at  $600^\circ\text{C}$ .

### 3.6.28. *Sc–Au–Si*

One ternary compound  $\text{ScAuSi}$  has been synthesized and its crystal structure was determined by Fornasini et al. (1992) (see table 19). There are no data about the phase equilibria in this system.

### 3.7. Sc–M–Ge ternary systems

#### 3.7.1. Sc–Li–Ge

The only data about the Sc–Li–Ge system concerns the ScLiGe ternary compound. Its crystal structure is presented in table 20 (overleaf). The phase diagram is unknown.

#### 3.7.2. Sc–Y–Ge

Shpyrka and Mokra (1991) published the isothermal section of the Sc–Y–Ge system at 600°C, which is shown in fig. 72. A continuous series of solid solutions occur between the isotypic binary compounds Sc<sub>5</sub>Si<sub>3</sub> and Y<sub>5</sub>Si<sub>3</sub>. Other binary germanides ScGe<sub>2</sub>, Sc<sub>11</sub>Ge<sub>10</sub>, Y<sub>2</sub>Ge<sub>3</sub> dissolve 18, 8, and 10 at.% Y or Sc, respectively. Three ternary compounds have been found. The crystal structures were determined for two compounds (see table 20).

Fig. 72. Sc–Y–Ge, isothermal section at 600°C. Ternary compounds: (1) Sc<sub>0.3</sub>Y<sub>0.7</sub>Ge<sub>2</sub>; (2) Sc<sub>1.35</sub>Y<sub>3.65</sub>Ge<sub>4</sub>; (3) Sc<sub>2.7</sub>Y<sub>2.3</sub>Ge<sub>4</sub>.

#### 3.7.3. Sc–La–Ge

Two Sc–La–Ge ternary compounds were synthesized, and their crystal structure data are given in table 20. There are no published data concerning the phase equilibria in this system.

#### 3.7.4. Sc–Ce–Ge

Bodak and Kokhan (1983) investigated the Sc–Ce–Ge isothermal section at 600°C; fig. 73 is based on these data. Four ternary compounds exist in this system; the crystal structures

<sup>a</sup> For the composition ScFe<sub>1.79</sub>Ge<sub>0.21</sub>.

Fig. 73. Sc-Ce-Ge, isothermal section at 600°C. Ternary compounds: (1)  $\sim$ Sc<sub>2</sub>Ce<sub>5</sub>Ge<sub>6</sub>; (2) ScCeGe; (3) Sc<sub>3</sub>Ce<sub>1.22</sub>Ge<sub>4</sub>; (4)  $\sim$ Sc<sub>4.5</sub>Ce<sub>0.5</sub>Ge<sub>4</sub>.

are known for two of them (see table 20). Shpyrka (1990) refined the composition of compound "Sc<sub>2</sub>CeGe<sub>3</sub>" to Sc<sub>3</sub>Ce<sub>1.22</sub>Ge<sub>4</sub>. This correction has been taken into account in fig. 73.

### 3.7.5. Sc-Pr(Sm)-Ge

In both the Sc-Pr-Ge and Sc-Sm-Ge ternary systems two ternary compounds of the same compositions and crystal structures occur (table 20). The phase equilibria have not been investigated.

### 3.7.6. *Sc-Nd-Ge*

The Sc-Nd-Ge phase equilibria at 600°C investigated by Bodak and Kokhan (1983) (presented in fig. 74), are similar to those of the system with cerium. However, the mutual solubility of Sc and Nd in the binary germanides reaches 10 at.% which is considerably higher than the solubility of Sc and Ce in binary germanides. Three ternary compounds are known in this system. The crystal structure data for two of them are given in table 20. However, the same group of authors reported different values for the lattice parameters for these compounds in different papers (see table 20).

Fig. 74. Sc-Nd-Ge, isothermal section at 600°C. Ternary compounds: (1)  $\sim$ Sc<sub>2</sub>Nd<sub>5</sub>Ge<sub>6</sub>; (2) ScNdGe; (3) Sc<sub>3</sub>Nd<sub>1.22</sub>Ge<sub>4</sub>.

### 3.7.7. *Sc-Eu-Ge*

The only ternary compound synthesized in the system, ScEuGe, belongs to the ScCeSi structure type (Shpyrka 1990) (see table 20). The phase diagram is still unknown.

### 3.7.8. *Sc-Dy-Ge*

As can be seen from fig. 75 which shows the phase equilibria in the Sc-Dy-Ge system at 600°C, there are many similarities with the Sc-Y-Ge system. Three ternary compounds of similar compositions and crystal structures occur in both systems (see table 20); these data were taken from Shpyrka and Mokra (1991).

### 3.7.9. *Sc-Yb-Ge*

The Sc-Yb-Ge isothermal section at 400°C investigated by Kotur and Mokra (1995) is presented in fig. 76. The immiscibility gap occurring in the Sc-Yb binary system spreads

Fig. 75. Sc–Dy–Ge, isothermal section at 600°C. Ternary compounds: (1)  $\text{Sc}_{0.3}\text{Dy}_{0.7}\text{Ge}_2$ ; (2)  $\text{Sc}_{1.8}\text{Dy}_{3.2}\text{Ge}_4$ ; (3)  $\text{Sc}_{2.7}\text{Dy}_{2.3}\text{Ge}_4$ .

Fig. 76. Sc–Yb–Ge, isothermal section at 400°C. Ternary compounds: (1)  $\sim\text{Sc}_{0.3}\text{Yb}_{0.7}\text{Ge}_2$ ; (2)  $\text{Sc}_6\text{Yb}_3\text{Ge}_{10}$ .

into the ternary system up to about 30 at.% Ge. The  $\text{Yb}_3\text{Ge}_5$  ( $\text{Th}_3\text{Pd}_5$  type) germanide dissolves about 6 at.% Sc. Large amounts of Yb (8 and 20 at.%) dissolve in the  $\text{ScGe}_2$

and the  $\text{Sc}_5\text{Ge}_3$  compounds, respectively. Two ternary compounds were observed in this system (table 20). For one of them,  $\text{Sc}_6\text{Yb}_5\text{Ge}_{10}$  the crystal structure has been determined by Kotur et al. (1996b), it crystallizes in the  $\text{Ho}_{11}\text{Ge}_{10}$  type of structure, the same as  $\text{Sc}_{11}\text{Ge}_{10}$ , however with a partial disorder of the Sc and the Yb atoms on the rare-earth sites.

### 3.7.10. Sc–Hf–Ge

Kotur (1991) studied the Sc–Hf–Ge isothermal section at  $800^\circ\text{C}$ , which is shown in fig. 77. Ternary compounds do not occur. Isotypic pairs of binary germanides  $\text{ScGe}_2$ – $\text{HfGe}_2$ ,  $\text{Sc}_5\text{Ge}_4$ – $\text{Hf}_5\text{Ge}_4$  and  $\text{Sc}_5\text{Ge}_3$ – $\text{Hf}_5\text{Ge}_3$  are completely miscible. Other Sc and Hf binary germanides dissolve appreciable quantities of the third component.

Fig. 77. Sc–Hf–Ge, isothermal section at  $800^\circ\text{C}$ .

### 3.7.11. Sc–V–Ge

The isothermal section at  $800^\circ\text{C}$ , which was determined by Kotur (1987), can be found in the review of Gladyshevsky et al. (1990). In contrast to the previous system the mutual solubility of Sc and V in the binary germanides is low and does not exceed 1 to 3 at.%. Kotur et al. (1983a) found a single crystal isotypic with  $\text{Sc}_5\text{Ge}_3$  in one of the ternary as-cast alloys. Its lattice spacings are  $a = 7.43$ ,  $c = 5.02 \text{ \AA}$ , but the proper composition is unknown. These data (Kotur 1987, Kotur et al. 1983a) indicate the large solubility of Sc in  $\text{V}_5\text{Ge}_3$  and V in  $\text{Sc}_5\text{Ge}_3$  at elevated temperatures. Two ternary compounds occur in the system. Their crystal structure data are in table 20.

### 3.7.12. Sc-Nb-Ge

The isothermal section at 800°C of the Sc-Nb-Ge system has been studied by Kotur (1986). The figure is presented also in Gladyshevsky et al. (1990). A solid solution of Nb in  $\text{Sc}_5\text{Ge}_3$  has been observed,  $\text{Sc}_{5-1.2}\text{Nb}_{0-3.8}\text{Ge}_3$ . The lattice parameters vary nonlinearly within the homogeneity range reaching the values of  $a=7.752$ ,  $c=5.365$  Å at  $\text{Sc}_{1.2}\text{Nb}_{3.8}\text{Ge}_3$ . One ternary compound,  $\text{Sc}_2\text{Nb}_3\text{Ge}_4$ , which is isotypic with  $\text{Sc}_3\text{Ce}_2\text{Si}_4$ , exists in this system (table 20).

### 3.7.13. Sc-Ta-Ge

Kotur and Bodak (1990) investigated the Sc-Ta-Ge isothermal section at 800°C which is displayed in fig. 78. The system is similar to the Nb-based one, however the solubility of Ta in  $\text{Sc}_5\text{Ge}_3$  is lower. The variation of the lattice parameters vs. composition of the solid solution  $\text{Sc}_{5-3.25}\text{Ta}_{0-1.75}\text{Ge}_3$  does not obey Vegard's rule, exhibiting a negative deviation. The only ternary compound, isotypic with  $\text{Sm}_5\text{Ge}_4$  has a variable Sc and Ta content. Its lattice spacings display a positive deviation from Vegard's rule. The limiting values of the lattice parameters are given in table 20.

Fig. 78. Sc-Ta-Ge, isothermal section at 800°C. Ternary compound: (1)  $\text{Sc}_{2-3}\text{Ta}_{3-2}\text{Ge}_4$ .

### 3.7.14. Sc-Cr-Ge

The isothermal section at 800°C of the Sc-Cr-Ge system has been studied by Kotur et al. (1988b) (fig. 79). The binary  $\text{Sc}_5\text{Ge}_3$  germanide dissolves 7.5 at.% Cr. A positive deviation from Vegard's rule is observed for the lattice parameters of this solid solution. Four ternary compounds exist in this system, their crystal structure data are shown in table 20. The compound  $\text{ScCrGe}_2$  (3) has been synthesized independently by Kotur et al. (1988b) and Venturini et al. (1985).

Fig. 79. Sc-Cr-Ge, isothermal section at 800°C. Ternary compounds: (1)  $\text{ScCr}_6\text{Ge}_6$ ; (2)  $\text{Sc}_2\text{Cr}_4\text{Ge}_5$ ; (3)  $\text{ScCrGe}_2$ ; (4)  $\text{Sc}_7\text{Cr}_{5.2}\text{Ge}_{8.8}$ .

### 3.7.15. Sc-Mo-Ge

Figure 80 displays the Sc-Mo-Ge isothermal section at 800°C according to the

Fig. 80. Sc-Mo-Ge, isothermal section at 800°C. Ternary compound: (1)  $\text{Sc}_{2.4}\text{Mo}_{3.1}\text{Ge}_4$ .

data of Kotur and Bodak (1988). The binary scandium and molybdenum germanides practically do not dissolve the third component at 800°C. Only  $\text{Sc}_5\text{Ge}_3$  forms a solid solution,  $\text{Sc}_{5-4.92}\text{Mo}_{0-0.08}\text{Ge}_3$ . One ternary compound isotypic with  $\text{Sm}_5\text{Ge}_4$  occurs:  $\text{Sc}_{2-4}\text{Mo}_{3-1}\text{Ge}_4$  with a variable content of Sc and Mo (table 20). It is separated by a two-phase region from the binary  $\text{Sc}_5\text{Ge}_4$  compound which crystallizes in the same structure.

### 3.7.16. Sc–W–Ge

The solubility of W in binary scandium germanides is not worth mentioning, except for  $\text{Sc}_5\text{Ge}_3$ , where a solid solution of up to 3 at.% W exists:  $\text{Sc}_{5-4.76}\text{W}_{0-0.24}\text{Ge}_3$ . No ternary compounds were observed in the ternary Sc–W–Ge system (fig. 81, Kotur et al. 1989a).

Fig. 81. Sc–W–Ge, isothermal section at 800°C.

### 3.7.17. Sc–Mn–Ge

Andrusyak and Kotur (1991) investigated a part of the Sc–Mn–Ge isothermal section at 600°C, which is presented in fig. 82. One ternary compound known earlier,  $\text{ScMnGe}_2$  (Meyer et al. 1983), has been confirmed, and five new ternary compounds have been obtained by Andrusyak and Kotur (see table 20). Later Kotur (1995) refined the composition of one compound, “ $\text{ScMn}_5\text{Ge}_3$ ” to  $\text{ScMn}_6\text{Ge}_4$ . This refinement was taken into account in fig. 82. The binary scandium germanides  $\text{ScGe}_2$ ,  $\text{Sc}_{11}\text{Ge}_{10}$  and  $\text{Sc}_5\text{Ge}_4$  dissolve 4, 2 and 3 at.% Mn, respectively. The other binary germanides do not dissolve appreciable quantities of the third component.

Fig. 82. Sc–Mn–Ge, isothermal section at 600°C. Ternary compounds: (1)  $\text{ScMn}_6\text{Ge}_6$ ; (2)  $\text{ScMn}_6\text{Ge}_4$ ; (3)  $\sim\text{Sc}_5\text{Mn}_7\text{Ge}_8$ ; (4)  $\text{ScMnGe}_2$ ; (5)  $\text{ScMnGe}$ ; (6)  $\text{Sc}_7\text{Mn}_{5.3}\text{Ge}_{8.7}$ .

### 3.7.18. Sc–Re–Ge

Venturini et al. (1985) reported about the ternary compound  $\text{ScReGe}_2$  isotypic with  $\text{ZrCrSi}_2$ . These data were confirmed by Kotur (1995). The lattice parameters reported in the two publications are in good agreement (table 20).

### 3.7.19. Sc–Fe–Ge

The Sc–Fe–Ge isothermal section at 600°C has been published by Andrusyak and Kotur (1991). All together eight ternary compounds were observed. Two of them,  $\text{ScFe}_6\text{Ge}_6$  and  $\text{ScFeGe}_2$  were synthesized earlier by Olenych et al. (1981) and Venturini et al. (1985), respectively. Using X-ray diffraction Kotur (1995) refined the compositions of two ternary compounds reported by Andrusyak and Kotur: “ $\text{ScFe}_5\text{Ge}_3$ ” to  $\text{ScFe}_6\text{Ge}_4$  and “ $\text{ScFe}_5\text{Ge}_4$ ” to  $\text{ScFe}_6\text{Ge}_5$ . The crystal structure data of the ternary compounds are given in table 20. Figure 83 shows an isothermal section at 600°C with the refined compositions of the ternary phases. Among binary scandium germanides only  $\text{ScGe}_2$  and  $\text{Sc}_5\text{Ge}_3$  dissolve a somewhat large amount of Fe: 6 at.%.

### 3.7.20. Sc–Co–Ge

The first data about this system were reported by Buchholz and Schuster (1981) and later by Venturini et al. (1985) who synthesized the following ternary compounds,  $\text{ScCo}_6\text{Ge}_6$  and  $\text{ScCoGe}_2$ , respectively. Kotur and Andrusyak (1991) investigated the isothermal section at 600°C which is shown in fig. 84. Seven ternary compounds were observed,

Fig. 83. Sc-Fe-Ge, isothermal section at 600°C. Ternary compounds: (1)  $\text{ScFe}_6\text{Ge}_6$ ; (2)  $\text{ScFe}_6\text{Ge}_5$ ; (3)  $\text{ScFe}_6\text{Ge}_4$ ; (4)  $\text{ScFeGe}_2$ ; (5)  $\text{Sc}_4\text{Fe}_4\text{Ge}_{6.6}$ ; (6)  $\text{Sc}_{1-1.17}\text{Fe}_{1.94-1.70}\text{Ge}_{0.06-0.30}$ ; (7)  $\text{ScFe}_{1.5}\text{Ge}_{0.5}$ ; (8)  $\text{ScFeGe}$ .

Fig. 84. Sc-Co-Ge, isothermal section at 600°C. Ternary compounds: (1)  $\text{ScCo}_6\text{Ge}_6$ ; (2)  $\sim\text{Sc}_4\text{Co}_{11}\text{Ge}_5$ ; (3)  $\text{Sc}_4\text{Co}_7\text{Ge}_6$ ; (4)  $\text{ScCoGe}_2$ ; (5)  $\text{Sc}_4\text{Co}_4\text{Ge}_6$ ; (6)  $\text{ScCoGe}$ ; (7)  $\text{Sc}_2\text{CoGe}_2$ .

five of them for the first time (table 20). Single crystals of a new ternary compound,  $\text{Sc}_3\text{Co}_2\text{Ge}_3$  were extracted from the alloy cooled at a rate of  $10\text{--}20^\circ\text{C}/\text{min}$  (Kotur and Andrusyak). Maybe this germanide exists over a narrow temperature range, which was not determined. The binary compounds  $\text{ScCo}_2$ ,  $\text{ScGe}_2$ ,  $\text{Sc}_{11}\text{Ge}_{10}$ ,  $\text{Sc}_5\text{Ge}_4$ ,  $\text{Sc}_5\text{Ge}_3$  dissolve 11.5 at.% Ge, and 6, 4, 4, and 3 at.% Co, respectively. The lattice parameter  $a$  of the solid solution  $\text{ScCo}_{2-1.65}\text{Ge}_{0-0.35}$  varies linearly from 6.902 to 6.984 Å (Kotur and Andrusyak 1991). The lattice spacings of the  $\text{ScCo}_{0-0.18}\text{Ge}_{2-1.82}$  solid solution also obey Vegard's rule.

### 3.7.21. *Sc–Ni–Ge*

The phase equilibria in the Sc–Ni–Ge system at  $600^\circ\text{C}$  have been investigated by Kotur and Andrusyak (1991) (see fig. 85). Eight ternary compounds occur at that temperature (table 20). From the as-cast samples single crystals of two other ternary compounds  $\text{Sc}_4\text{Ni}_4\text{Ge}_{6.2}$  and  $\text{Sc}_9\text{Ni}_5\text{Ge}_8$  have been extracted and their crystal structures have been determined by Andrusyak and Kotur (1989) and Kotur et al. (1989d), respectively (table 20). The binary scandium germanides dissolve from 2 to 8 at.% Ni,  $\text{ScNi}_2$  dissolves about 3.5 at.% Ge.

Fig. 85. Sc–Ni–Ge, isothermal section at  $600^\circ\text{C}$ . Ternary compounds: (1)  $\text{ScNi}_6\text{Ge}_6$ ; (2)  $\text{Sc}_{12.3}\text{Ni}_{40.7}\text{Ge}_{31}$ ; (3)  $\text{Sc}_3\text{Ni}_{11}\text{Ge}_4$ ; (4)  $\text{Sc}_6\text{Ni}_{18}\text{Ge}_{11}$ ; (5)  $\text{Sc}_6\text{Ni}_{16}\text{Ge}_7$ ; (6)  $\text{Sc}_3\text{Ni}_4\text{Ge}_4$ ; (7)  $\text{ScNiGe}$ ; (8)  $\sim\text{Sc}_{13}\text{Ni}_6\text{Ge}_{15}$ .

### 3.7.22. *Sc–Ru(Rh, Pd, Os, Ir)–Ge*

There are no literature data concerning the phase diagrams of Sc–M–Ge for  $M = \text{Ru}, \text{Rh}, \text{Pd}, \text{Os},$  or  $\text{Ir}$ . From one to three ternary compounds have been synthesized in each of these

systems. Their crystal structure data are presented in table 20. The ScRhGe compound, possibly, occurs in two polymorphic modifications. The temperature of the phase transition is unknown.

### 3.7.23. Sc–Cu–Ge

Kotur and Andrusyak (1984b) investigated the Sc–Cu–Ge isothermal section at 600°C; the figure is also shown in the review of Gladyshevsky et al. (1990). Two ternary compounds have been found (table 20). Dwight (1968) was the first to report on the ScCuGe compound. Another germanide, Sc<sub>3</sub>Cu<sub>4</sub>Ge<sub>4</sub> was synthesized independently by Thirion et al. (1983) and Kotur and Andrusyak (1984b). The data on the lattice spacings of these ternaries obtained by different authors are in good agreement (table 20).

### 3.7.24. Sc–Ag–Ge

One ternary compound, ScAgGe, exists at 600°C according to the data of Kotur and Boichuk (1988) (fig. 86, table 20). The mutual solubility of the components in Sc–Ag and Sc–Ge binary compounds is practically zero.

Fig. 86. Sc–Ag–Ge, isothermal section at 600°C. Ternary compound: (1) ScAgGe.

## 3.8. Sc–M–Sn ternary systems

### 3.8.1. Sc–Li–Sn

The data published by Grund (1985) about the ternary compound, ScLiSn, which is isotopic with MgAgAs (table 21) are the only data known for the Sc–Li–Sn system.

Table 21  
Intermetallic compounds in the Sc–M–Sn ternary systems

<sup>a</sup> lattice parameter of pseudocubic cell.

### 3.8.2. *Sc–Mn–Sn*

The Sc–Mn–Sn phase diagram is unknown, but one ternary compound, ScMn<sub>6</sub>Sn<sub>6</sub> has been synthesized and its crystal structure determined (Malaman et al. 1988) (table 21).

### 3.8.3. *Sc–Fe–Sn*

Kotur and Klyuchka (1989) investigated alloys of the compositions ScFeSn, ScFe<sub>2</sub>Sn and ScFe<sub>4</sub>Sn, but no ternary compounds of such stoichiometries were found. Malaman et al. (1988) reported the existence and the crystal structure of the ternary compound ScFe<sub>6</sub>Sn<sub>6</sub> (table 21). There are no data in the literature about the phase equilibria in this system.

### 3.8.4. *Sc–Co–Sn*

There are data in the literature about four ternary Sc–Co–Sn compounds (see table 21). Espinosa et al. (1982) reported the lattice parameter of a pseudocubic unit cell for a compound with the tentative composition ScCo<sub>1.1</sub>Sn<sub>3.6</sub>. Rare earths form numerous groups of closely related ternary compounds of such a stoichiometry which crystallize in different cubic and tetragonal structure types. A single-crystal investigation is necessary to determine the actual crystal structure of ScCo<sub>1.1</sub>Sn<sub>3.6</sub>. The data of Kotur and Klyuchka (1989) and Dwight and Kimball (1987) concerning ScCo<sub>2</sub>Sn are in good agreement with each other (table 21). According to the data of Kotur and Klyuchka this ternary compound is in equilibrium with Co at 400°C.

### 3.8.5. *Sc–Ni–Sn*

Four ternary compounds in the Sc–Ni–Sn system have been synthesized and structurally investigated (table 21). However, there are only few data known about the phase equilibria. Kotur and Klyuchka (1989) reported that at 400°C the ScNi<sub>4</sub>Sn stannide is in equilibria with Ni and ScNi<sub>2</sub>Sn. The latter compound is also in equilibrium with ScNiSn. Derkach and Kotur (1994) also found that at 400°C the Sc<sub>2</sub>Ni<sub>2</sub>Sn ternary compound is in equilibria with the ternary phase ScNiSn and also with the binary phases ScNi<sub>2</sub>, ScNi and Sc<sub>5</sub>Sn<sub>3</sub>.

### 3.8.6. *Sc–Ru(Rh, Pd, Os, Ir, Pt)–Sn*

The phase equilibria of the Sc–M–Sn (where M = Ru, Rh, Pd, Os, Ir, or Pt) systems are not known. One or two ternary compounds have been synthesized in each of the systems. These data are shown in table 21. Espinosa et al. (1982) reported on the tetragonal ternary compounds of a tentative composition ScM<sub>1.1</sub>Sn<sub>3.6</sub> (M = Ru, Rh, Ir) giving their pseudocubic cell parameters (table 21). Probably, these compounds are isotypic with Er<sub>5–x</sub>Rh<sub>6</sub>Sn<sub>18+x</sub> found by Hodeau and Marezio (1984), however, additional investigations are necessary to determine the proper composition and structure of these stannides. Two and three different crystal structure types have been reported for ScPdSn and ScPtSn, respectively (see table 21). This might be an indication for a polymorphism of these compounds.

Fig. 87. Sc–Cu–Sn, isothermal section at 400°C. Ternary compounds: (1) ScCu<sub>4</sub>Sn; (2) ScCuSn; (3) ~Sc<sub>6</sub>CuSn<sub>2</sub>.

### 3.8.7. Sc–Cu–Sn

The Sc–Cu–Sn system is the only one of the Sc–M–Sn series for which an isothermal section at 400°C has been reported (fig. 87, Kotur and Derkach 1994). Three ternary compounds occur, and for two of the compounds the crystal structure is known (table 21).

### 3.8.8. Sc–Au–Sn

The existence of a cubic ternary compound of equiatomic composition (ScAuSn) has been reported by Dwight (1976) and by Eberz et al. (1980). In both publications the same lattice parameter  $a = 6.422 \text{ \AA}$  is mentioned, however for different structure types, MgAgAs (Dwight) and AlLiSi (Eberz et al.) (table 21).

## 3.9. Sc–M–P(As, Sb, Bi) ternary systems

### 3.9.1. Sc–Gd–P

Jansen and Sperlich (1975) reported about a continuous series of solid solutions between isotypic binary phosphides ScP and GdP, these are the only data known about this system.

### 3.9.2. Sc–Mn(Fe, Co)–P

No data exist for the Sc–M–P (M=Mn, Fe and Co) phase equilibria. Jeitschko et al. (1993, 1990), Reinbold and Jeitschko (1987) and Jeitschko and Reinbold (1985) reported

Table 22

ScNiBi	MgAgAs	6.191			Dwight (1974)
ScPdBi	MgAgAs	6.4353			Block et al. (1990)

on one, three and four ternary compounds and their crystal structures in the Mn, Fe and Co systems, respectively. These data are shown in table 22.

### 3.9.3. Sc–Ru–P

Ghetta et al. (1986) synthesized two ternary compounds, Sc<sub>2</sub>Ru<sub>12</sub>P<sub>7</sub> and ScRuP, and established their crystal structure (table 22). The phase equilibria for Sc–Ru–P alloys are unknown.

### 3.9.4. Sc–Ni–As

One ternary compound ScNi<sub>4</sub>As<sub>2</sub> has been synthesized by Jeitschko et al. (1990) (table 22). This paper is the only one about ternary alloys with scandium and arsenic.

### 3.9.5. Sc–Ni(Pt, Au)–Sb

Isothermal sections of the Sc–M–Sb (M=Ni, Pt and Au) systems have not been investigated. Only a few alloys were examined, among them the compounds ScNiSb and ScPtSb have been synthesized by Dwight (1974) and Pecharsky et al. (1983) (table 22). Later Dwight (1977) reported that no compound of Sc<sub>3</sub>Au<sub>3</sub>Sb<sub>4</sub> composition exists.

### 3.9.6. *Sc-Ni(Pd)-Bi*

In both the Sc-Ni-Bi and Sc-Pd-Bi systems the compounds with the equiatomic composition have been obtained by Dwight (1974) and Block et al. (1990). Their crystal structure data are given in table 22. There are no literature data for the phase equilibria in any of the Sc-M-Bi ternary system.

### 3.10. *Sc-M-Se ternary systems*

#### 3.10.1. *Sc-Mg(Eu, Mn, Cu, Ag, Cd)-Se*

None of the Sc-M-Se (M = Mg, Eu, Mn, Cu, Ag and Cd) ternary systems was investigated systematically. Only separate alloys have been examined with respect to the occurrence of ternary compounds known to exist in other related ternary systems. As a result one ternary compound in the six systems has been reported. These data are given in table 23.

Table 23  
Intermetallic compounds in the Sc-M-Se ternary systems

Compound	Structure type or symmetry	Lattice parameters			Reference

### 3.11. *Sc-X-X'* ternary systems

#### 3.11.1. *Sc-Ga-Al*

Markiv et al. (1987) reported about a part of the Sc-Ga-Al isothermal section at 900°C (25–100 at.% Sc), which is depicted in fig. 88. Four ternary compounds were observed and for two of them (Nos. 1 and 4 in fig. 88) the crystal structure has been determined (table 24). The binary compound ScGa<sub>2</sub> (ST KHg<sub>2</sub>) dissolves 22 at.% Al. The lattice spacings of the solid solution ScGa<sub>2-x</sub>Al<sub>x</sub> increase from *a* = 4.140, *b* = 6.614, *c* = 7.914 to *a* = 4.143, *b* = 6.618, *c* = 7.922 Å. Another binary gallide, Sc<sub>5</sub>Ga<sub>4</sub> (ST Ho<sub>11</sub>Ge<sub>10</sub>) dissolves about 12 at.% Al. The lattice parameters *a* and *c* vary within the limits 10.366–10.395 and 15.305–15.305 Å. Sc<sub>5</sub>Ga<sub>3</sub> (ST Mn<sub>5</sub>Si<sub>3</sub>) dissolves about 20 at.% Al: *a* = 8.07–8.162, *c* = 5.951–5.923 Å, respectively. The solubility of Al in Sc<sub>3</sub>Ga<sub>2</sub> (ST Gd<sub>3</sub>Ga<sub>2</sub>) is about 13 at.%, the lattice parameters of the solid solution vary from *a* = 10.767, *c* = 14.045 to *a* = 10.781, *c* = 14.131 Å. A large amount of Ga (about 15 at.%) can be dissolved by ScAl<sub>2</sub>

Fig. 88. Sc-Ga-Al, part of the isothermal section at 900°C (25–100 at.% Si). Ternary compounds: (1)  $\text{ScGa}_{0.75-1.23}\text{Al}_{1.25-0.77}$ ; (2)  $\sim\text{Sc}_4\text{Ga}_4\text{Al}$ ; (3)  $\sim\text{ScGa}_{0.56-0.64}\text{Al}_{0.44-0.36}$ ; (4)  $\text{ScGa}_{0.4}\text{Al}_{0.6}$ .

(ST  $\text{MgCu}_2$ ):  $a = 7.580\text{--}7.552 \text{ \AA}$ . A compound of the approximate ScAl composition (55 at.% Al) dissolves up to 7 at.% Ga. The isotypic binary compounds ScGa<sub>3</sub> and ScAl<sub>3</sub> (ST  $\text{AuCu}_3$ ) are completely miscible.

### 3.11.2. Sc-C-B(Al)

No data are known about phase equilibria in the Sc-C-B and Sc-C-Al systems. However, three and two ternary compounds have been synthesized and structurally investigated in the boron and aluminium systems, respectively. These data are presented in table 24. Bauer (1982) observed also a solid solution of C in ScB<sub>2</sub>:  $\text{ScB}_{2-1.9}\text{C}_{0-0.1}$ .

### 3.11.3. Sc-In(Tl, Sn, Pb)-B

Holleck (1977) reported the existence of a ternary compound of the tentative composition  $\text{Sc}_3\text{XB}_{1-x}$  of the perovskite type structure in the Sc-X-B (X = In, Tl, Sn and Pb) systems (table 24). The actual composition, however, is unknown due to the evaporation of the components during the synthesis procedure. The alloys were homogenized at 800°C.

### 3.11.4. Sc-In(Tl, Sn, Pb)-C

Holleck (1977) synthesized the ternary  $\text{Sc}_3\text{XC}_x$  (X = In, Tl, Sn and Pb) compounds which are isotypic with  $\text{CaTiO}_3$  (table 24). However, the exact content of carbon in these compounds is unknown.

Table 24

Sc <sub>11</sub> Al <sub>2</sub> Ge <sub>8</sub>	Sc <sub>11</sub> Al <sub>2</sub> Ge <sub>8</sub>	10.419		14.974	Zhao and Parthé (1991)

### 3.11.5. Sc–Si–C

Kotroczo and McColm (1987) investigated solubility of carbon in Sc<sub>5</sub>Si<sub>3</sub> (ST Mn<sub>5</sub>Si<sub>3</sub>) and observed a solid solution, Sc<sub>5</sub>Si<sub>3</sub>C<sub>0–0.8</sub>. The lattice parameters vary nonlinearly within the homogeneity range:  $a = 7.876–7.877$ ,  $c = 5.821–5.902$  Å.

### 3.11.6. Sc–Al–Si

Toropova et al. (1985) established part of the polythermal section of the Sc–Al–Si system at a constant content of 2 at.% Al. They observed a ternary phase of unknown composition. Its crystal structure was determined in a detailed structural investigation which showed that it had the Sc<sub>2</sub>AlSi<sub>2</sub> composition (Tyvanchuk et al. 1988) (table 24). These authors published also the isothermal section at 500°C, which is shown in fig. 89.

### 3.11.7. Sc–Ge–Si

Muratova (1978) studied the Sc–Ge–Si isothermal section at 600°C, however, no figure was presented in her paper. A continuous series of solid solutions exist between pairs of isotypic binary compounds Sc<sub>5</sub>Ge<sub>3</sub> and Sc<sub>5</sub>Si<sub>3</sub>, ScGe and ScSi. The scandium germanide

Fig. 89. Sc-Al-Si, isothermal section at 500°C. Ternary compound: (1)  $\text{Sc}_2\text{AlSi}_2$ .

with the highest Ge content,  $\text{ScGe}_2$ , dissolves 35 at.% Si. The lattice spacings of these solid solutions vary linearly within their homogeneity ranges. Ternary compounds have not been observed.

### 3.11.8. Sc-Al-Ge

The ternary compound  $\text{Sc}_{11}\text{Al}_2\text{Ge}_8$  with one of the superstructures of the  $\text{Ho}_{11}\text{Ge}_{10}$  type has been synthesized and investigated by Zhao and Parthé (1991). The lattice parameters are given in table 24. Phase equilibria are unknown.

### 3.11.9. Sc-As-P

Yim et al. (1972) found a continuous series of solid solutions between the isotopic binary compounds ScP and AsP. These are the only data known about this system.

### 3.11.10. Sc-Te-Se

Dismukes and White (1965) obtained the alloy  $\text{Sc}_2\text{Te}_{0.33}\text{Sc}_{2.67}$  at 950–1000°C with the structure of  $\text{Sc}_2\text{Se}_3$  and the lattice parameters  $a = 10.915$ ,  $b = 7.729$  and  $c = 23.12$  Å. These data indicate the occurrence of a solid solution  $\text{Sc}_2\text{Te}_x\text{Se}_{2-x}$  ( $0 \leq x \leq 0.33$ ). A substitution of Te for Se leads to an increase of the lattice constants.

### 3.12. *Sc–M–M'* ternary systems

#### 3.12.1. *Sc–Mg–Mn*

Drits et al. (1977) reported on the isothermal sections at 500 and 300°C in the magnesium corner of this system. The solubility of Sc and Mn decrease as a result of their alloying with Mg. Four phases in a peritectic nonvariant equilibrium  $L + \beta \leftrightarrow \alpha + \text{Mn}$  ( $\beta$ : solid solution of Mg in  $\beta\text{Sc}$ ) at 700°C have been detected.

#### 3.12.2. *Sc–Y–Gd*

A single crystal with the composition  $\text{Sc}_{0.075}\text{Y}_{0.175}\text{Gd}_{0.75}$  with the hcp structure has been prepared and its magnetic properties investigated by Ito et al. (1988), however, no data about the lattice parameters were presented in this paper. These data indicate a complete miscibility of the components in the ternary system, similar to what occurs in the binary Sc–Y and Sc–Gd systems (see sect. 2.3).

#### 3.12.3. *Sc–Tb–Mn*

Lelievre-Berna et al. (1993) prepared two alloys of the solid solution  $\text{Tb}_{1-x}\text{Sc}_x\text{Mn}_2$  ( $x=0.00, 0.01$  and  $0.03$ ) (ST  $\text{MgCu}_2$ ) and investigated their magnetic structures. The alloys, annealed at 730°C, were essentially single phase according to the X-ray powder diffraction analysis, however, a small amount of pure Tb metal was detected by neutron scattering. These data indicate the occurrence of a limited solid solution of Sc in  $\text{TbMn}_2$ . No data about variation of lattice parameter are available.

#### 3.12.4. *Sc–Y–Fe*

The isothermal section of the Sc–Y–Fe system at 600°C, which is presented in fig. 90, has been established by Koshel' et al. (1984). The phase equilibria at 800°C are the same. Ternary compounds were not observed. The highest solubility of Sc, 30 at.%, occurs in the binary  $\text{YFe}_2$  (ST  $\text{MgCu}_2$ ) compound. The lattice parameter  $a$  changes within the limits 7.358–7.037 Å. Other Y–Fe binary compounds do not dissolve more than 5 at.% Sc.

#### 3.12.5. *Sc–Ce–Fe*

Figure 91 displays the Sc–Ce–Fe isothermal section at 600°C, which was investigated by Koshel' et al. (1984). This system is similar to the previous Y-based one.  $\text{CeFe}_2$  (ST  $\text{MgCu}_2$ ) dissolves about 22 at.% Sc. The lattice parameter  $a$  of the solid solution  $\text{Ce}_{1-0.33x}\text{Sc}_{0-0.67x}\text{Fe}_2$  changes within the limits 7.272–7.159 Å.  $\text{ScFe}_2$  dissolves less than 5 at.% Ce. Ternary compounds have not been reported. The same phase equilibria were observed at 800°C.

#### 3.12.6. *Sc–U–Pd*

Maple et al. (1996) reported about a solid solution of Sc in the binary compound  $\text{UPd}_3$  (ST  $\text{AuCu}_3$ ),  $\text{U}_{1-x}\text{Sc}_x\text{Pd}_3$  ( $0 \leq x \leq 0.5$ ). Data concerning the variation of the lattice parameter with the composition were not presented. Dhar et al. (1996) reported about an alloy

Fig. 90. Sc-Y-Fe, isothermal section at 600°C.

Fig. 91. Sc-Ce-Fe, isothermal section at 600°C.

with the composition  $\text{Sc}_{0.8}\text{U}_{0.2}\text{Pd}_3$  crystallizing in the cubic  $\text{AuCu}_3$  type structure with the lattice parameter  $a = 3.980 \text{ \AA}$ . These data support the occurrence of the  $\text{Sc}_{1-x}\text{U}_x\text{Pd}_3$  ( $0 \leq x \leq ?$ ) solid solution.

3.12.7. *Sc-Ti-Fe*

Nishihara and Yamaguchi (1985, 1986) reported the occurrence of the complete miscibility of the isotypic binary compounds  $\text{ScFe}_2$  and  $\text{TiFe}_2$  (ST  $\text{MgZn}_2$ ). However, no data about lattice parameters of the solid solution were presented. The  $\text{ScFe}_2$ - $\text{TiFe}_2$  magnetic phase diagram has been studied in detail, see sect. 6.

3.12.8. *Sc-Ti-Ni*

The melting diagram of the  $\text{Sc-Ti-Ni}$  system in the range of 50–100 at.% Ni has been investigated by Semenova et al. (1996b). Two ternary eutectics and two ternary peritectics occur at 1110 and 980°C, and 1210 and 1130°C, respectively. Semenova et al. (1996a) investigated the system for the same concentration range at the subsolidus temperatures. No ternary compounds were observed. The solid solubility limits of the phases based on the binary compounds were determined. The polythermal section  $\text{TiNi-ScNi}$  was shown to be quasibinary.

3.12.9. *Sc-Ti-Pt*

Dwight (1961b) investigated the alloys of the section  $\text{ScPt}_3$ - $\text{TiPt}_3$  at 900°C. The isotypic binary compounds of the  $\text{AuCu}_3$  structure type are completely miscible. Other regions of the diagram were not investigated.

3.12.10. *Sc-Hf-Ir*

Dwight et al. (1963b) synthesized one ternary compound,  $\text{Sc}_{0.2}\text{Hf}_{0.8}\text{Ir}$  and showed that it crystallizes in the  $\gamma\text{TiCu}$  type structure (table 25). These are the only data known about this system.

Table 25  
Intermetallic compounds in the  $\text{Sc-M-M}'$  ternary systems

Compound	Structure type or symmetry	Lattice parameters		Reference
		$a$ (Å)	$c$ (Å)	
$\text{Sc}_{0.2}\text{Hf}_{0.8}\text{Ir}$	$\gamma\text{TiCu}$	3.32	6.22	Dwight et al. (1963b)
$\text{ScNi}_4\text{Au}$	$\text{MgCu}_4\text{Sn}$	6.828		Dwight (1975)
$\text{ScCuZn}$ (I)	$\text{MgZn}_2$	5.164	8.364	Dwight (1968)
$\text{ScCuZn}$ (II)	$\text{CaIn}_2$	4.39	6.82	Dwight (1968)

3.12.11. *Sc-V-Nb*

According to the investigations of Savitskii et al. (1975) ternary compounds do not exist in this system. A narrow region of continuous series of solid solutions adjoining the  $\text{V-Nb}$  binary system was observed in the ternary system. The solubility of scandium in  $\text{V(Nb)}$  solid solution decrease from 2 at.% in binary  $\text{Sc-V}$  alloys to 0.1 at.% in binary  $\text{Sc-Nb}$  alloys. The lowest solubility of scandium occurs in the  $\text{V}_{20}\text{Nb}_{80}$  alloy.

### 3.12.12. *Sc-Cr-Ni*

Maslenkov and Braslavskaya (1986a) reported on the Sc-Cr-Ni phase diagram in the temperature range 1100–1860°C. The quasibinary sections Cr-ScNi<sub>2</sub> and Cr-Sc<sub>2</sub>Ni<sub>7</sub> are of eutectic type. The isothermal section at 1300°C and the projection of a part of the liquidus surface (Ni-Cr-ScNi<sub>2</sub>) are presented in the paper too. The lowest ternary eutectic  $L \leftrightarrow \gamma_{\text{Ni}} + \langle \text{ScNi}_5 \rangle + \langle \text{Sc}_2\text{Ni}_7 \rangle$  occurs at 1125°C. The same authors (Maslenkov and Braslavskaya 1986b) presented parts (Ni-Cr-ScNi<sub>2</sub>) of isothermal sections at 800 and 1050°C. The figure of the latter is shown in the review of Gladyshevsky et al. (1990). These isothermal sections differ from one another due to the rapid decrease of the solubility of scandium in the Ni(Cr) solid solution ( $\gamma_{\text{Ni}}$  phase), which is 0.27 and 0.1 at.% at 1050 and 800°C, respectively. Ternary compounds were not observed. Part of the alloys of the three-phase region ScNi<sub>5</sub>-Ni-Cr were inhomogeneous.

### 3.12.13. *Sc-Mn-Fe*

Kyrchiv (1983) reported about an investigation of part of the Sc-Mn-Fe isothermal section at 600°C (0–33.3 at.% Sc), however, no figure was presented. Isotypic binary compounds ScMn<sub>2</sub> and ScFe<sub>2</sub> (ST MgZn<sub>2</sub>) are completely miscible. No ternary compounds were observed.

### 3.12.14. *Sc-Re-Ni*

Part of the Sc-Re-Ni isothermal section at 1000°C (Ni corner) has been studied by Arskaya et al. (1970) and Savitskii et al. (1972). Ternary compounds do not occur. The solubility of Sc in Ni is about 0.2 wt.%, and it decreases rapidly with increasing rhenium content. Nickel dissolves up to 40 wt.% Re.

### 3.12.15. *Sc-Ru-Rh*

Khorujaya and Korniyenko (1996, 1997) reported on part of the projection of the liquidus surface (0–50 at.% Sc). The projection of the solidus surfaces in the same concentration region has been determined by Eremenko et al. (1996). Ternary compounds do not exist. The liquidus surface consists of five surfaces of primary crystallization of Ru and Rh solid solutions as well as of the phases based on ScRu<sub>2</sub>, ScRh<sub>3</sub> and on a continuous series of solid solutions between the isotypic compounds ScRu and ScRh ( $\delta$  phase). The highest temperature on the surface is 2334°C (Ru melting point) and the lowest one is 1520°C (ternary eutectic  $L(E_1) \leftrightarrow \delta + \langle \text{ScRh}_3 \rangle + \langle \text{Ru} \rangle$ ).

### 3.12.16. *Sc-Ni-Au*

One ternary compound ScNi<sub>4</sub>Au has been synthesized and structurally investigated by Dwight (1975) (table 25). These are the only data reported about this system.

### 3.12.17. *Sc-Cu-Zn*

Dwight (1968) reported that the ternary compound ScCuZn exists in two polymorphic modifications. Their crystal structure data are presented in table 25. Phase equilibria have not been investigated.

## 4. Multicomponent systems containing scandium

Little information has been published in the literature concerning four-component systems containing scandium. The starting material for the preparation of multicomponent (four-component) alloys is normally a pair of ternary compounds. Multicomponent systems are frequently prepared if one (or both) ternary system show outstanding physical properties, such as superconductivity with high transition temperatures, a possible coexistence of superconductivity and magnetism, or if the multicomponent system can be used for hard magnetic materials. In that cases the effect of alloying on the properties of ternary compound is examined in a four-component system. Data about five-component systems containing scandium are even more rare.

### 4.1. *Sc-Mg-Mn-Li(Ca, Y, Ce, Nd, Zr, Ni, Cd, Zn, Al, In, Si, Ge, Sn)*

Drits et al. (1971) investigated the effect of alloying on the properties (tensile and yield strengths, elongation and hardness) at ambient and elevated (300–350°C) temperatures of multiphase Mg-based ternary alloys Mg + 11%Sc + 1.0%Mn and Mg + 11%Sc + 0.6%Mn (composition in wt.%). The quantities of the alloyed elements did not exceed 2 wt.%. Additions of 0.5–1.0% Ca, Cd, Si, Y and Zn increase the strength of Mg + 11%Sc + 0.6%Mn alloy at ambient temperature. Additions of 0.5–1.0% rare earths, Zn and Sn had the same effect on the strength at 350°C. Additions of Li, Al and Sn (in larger amounts) have a negative influence. This improvement in the mechanical properties is attributed to the appearance of noticeable amounts of second phase intermetallic compounds, especially in the case of Al. Additions of Zr, Ni, In and Ge practically do not have an effect on the strength of these ternary Mg-Sc-Mn alloys.

### 4.2. *Sc-Ca-Rh-B*

Matthias et al. (1978) obtained the compound  $\text{Sc}_{0.3}\text{Ca}_{0.7}\text{Rh}_4\text{B}_4$  occurring in two polymorphic modifications. However, their structures and lattice spacings were not reported. One of the phases, probably HT, is of  $\text{CeCo}_4\text{B}_4$  type structure (Vandenberg and Matthias 1977).

### 4.3. *Sc-Ce(Pr, Nd, Sm, Gd, Tb, Dy, Ho, Er, Tm)-Rh-B*

Matthias et al. (1978) prepared the alloys with the compositions  $\text{Sc}_x\text{R}_{1-x}\text{Rh}_4\text{B}_4$  ( $x = 0.2, 0.3, 0.4$ ). Compositions of single phase alloys for different R are presented in

Table 26

Compositions of single phase alloys prepared in the Sc-R-Rh-B systems (R=Ce, Pr, Nd, Sm, Gd, Tb, Dy, Ho, Er, Tm)<sup>a</sup>

Composition of alloy	Modification	Composition of alloy	Modification
Sc <sub>0.3</sub> Ce <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	HT	Sc <sub>0.3</sub> Dy <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	HT
Sc <sub>0.3</sub> Pr <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	HT	Sc <sub>0.3</sub> Ho <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	LT
Sc <sub>0.3</sub> Nd <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	HT	Sc <sub>0.4</sub> Ho <sub>0.6</sub> Rh <sub>4</sub> B <sub>4</sub>	HT
Sc <sub>0.3</sub> Sm <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	HT+LT	Sc <sub>0.2</sub> Er <sub>0.8</sub> Rh <sub>4</sub> B <sub>4</sub>	HT
Sc <sub>0.3</sub> Gd <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	LT	Sc <sub>0.3</sub> Er <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	?
Sc <sub>0.3</sub> Tb <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	HT	Sc <sub>0.3</sub> Tm <sub>0.7</sub> Rh <sub>4</sub> B <sub>4</sub>	HT

<sup>a</sup> Source: Matthias et al. (1978).

table 26. One of the two modifications of compounds is tetragonal. However, the original paper does not indicate which of them, and neither gives the data about their lattice spacings. Taking into account the data of Vandenberg and Matthias (1977) about the occurrence of ternary compounds RRh<sub>4</sub>B<sub>4</sub> (R=Nd, Sm, Gd, Tb, Dy, Ho, Er, Tm) with the tetragonal structure of the CeCo<sub>4</sub>B<sub>4</sub> type (SG *P4<sub>2</sub>/nmc*), it is possible to state that the formation of solid solutions occur when R is substituted for Sc in these ternary compounds, Sc<sub>x</sub>R<sub>1-x</sub>Rh<sub>4</sub>B<sub>4</sub>. These solutions are metastable (Matthias et al. 1978). Additional investigation is necessary to establish their homogeneity regions. Possibly, Sc<sub>0.3</sub>Ce<sub>0.7</sub>Rh<sub>4</sub>B<sub>4</sub> and Sc<sub>0.3</sub>Pr<sub>0.7</sub>Rh<sub>4</sub>B<sub>4</sub> are individual quaternary compounds; however there is no data about the occurrence of ternary compounds CeRh<sub>4</sub>B<sub>4</sub> and PrRh<sub>4</sub>B<sub>4</sub>.

#### 4.4. Sc-Y(Nd, Dy, Er, Lu)-Fe-B

Chen and Duh (1988) reported the occurrence of the solid solution (Sc<sub>0-0.2</sub>R<sub>1-0.8</sub>)<sub>2</sub>Fe<sub>14</sub>B at 1000°C and variations of the lattice spacings within its homogeneity range (see table 27). The alloys are ferromagnetic. The Curie temperature of the alloys monotonically decrease with the increasing scandium content (see table 27).

Table 27

Variations of lattice parameters and Curie temperature (*T<sub>C</sub>*) within the homogeneity ranges of the solid solutions (Sc<sub>0-0.2</sub>R<sub>1-0.8</sub>)<sub>2</sub>Fe<sub>14</sub>B (R=Y, Nd, Dy, Er, Lu) which are isotypic with Nd<sub>2</sub>Fe<sub>14</sub>B

Solid solution	Lattice parameters (Å)		<i>T<sub>C</sub></i>
	<i>a</i>	<i>c</i>	
(Sc <sub>0-0.2</sub> Y <sub>1-0.8</sub> ) <sub>2</sub> Fe <sub>14</sub> B	8.767-8.750	12.037-11.988	564-557
(Sc <sub>0-0.2</sub> Nd <sub>1-0.8</sub> ) <sub>2</sub> Fe <sub>14</sub> B	8.792-8.769	12.190-12.186	589-585
(Sc <sub>0-0.2</sub> Dy <sub>1-0.8</sub> ) <sub>2</sub> Fe <sub>14</sub> B	8.762-8.756	12.022-11.977	592-583
(Sc <sub>0-0.2</sub> Er <sub>1-0.8</sub> ) <sub>2</sub> Fe <sub>14</sub> B	8.738-8.730	11.964-11.917	553-544
(Sc <sub>0-0.2</sub> Lu <sub>1-0.8</sub> ) <sub>2</sub> Fe <sub>14</sub> B	8.703-8.656	11.876-11.893	535-528

#### 4.5. *Sc–Lu–Ru–B*

The as-cast and homogenized at 1150°C Sc–Lu–Ru–B alloys of the section “ScRu<sub>4</sub>B<sub>4</sub>”–LuRu<sub>4</sub>B<sub>4</sub> have been examined by Ku et al. (1979). The boundary ternary compound LuRu<sub>4</sub>B<sub>4</sub> (ST LuRu<sub>4</sub>B<sub>4</sub>, SG *I4<sub>1</sub>/acd*) is thermodynamically stable while the compound “ScRu<sub>4</sub>B<sub>4</sub>” is metastable and decomposes after homogenization at 800–1300°C. A metastable continuous series of solid solutions Sc<sub>0–1</sub>Lu<sub>1–0</sub>Ru<sub>4</sub>B<sub>4</sub> occur. The lattice parameters vary within the limits  $a=7.419\text{--}7.346$  and  $c=14.955\text{--}14.895$  Å. All the alloys are superconducting. More details are given in sect. 6.

#### 4.6. *Sc–U–Pd–B*

Five alloys Sc<sub>0.8</sub>U<sub>0.2</sub>Pd<sub>3</sub>B<sub>x</sub> ( $x=0, 0.1, 0.2, 0.3, 0.5$ ) have been prepared by Dhar et al. (1996). An X-ray phase examination shows the occurrence of the Sc<sub>0.8</sub>U<sub>0.2</sub>Pd<sub>3</sub>B<sub>x</sub> ( $0 \leq x \leq 0.3$ ) solid solution of AuCu<sub>3</sub> type structure with the lattice constants 3.980, 3.999 and 4.017 Å for  $x=0, 0.1$  and 0.3, respectively. The non-Fermi liquid behaviour reported in the literature for  $x=0$  alloy (Gajewski et al. 1994) persists in  $x=0.1$ , but is absent in  $x=0.2$  and 0.3 alloys at least down to 1.4 K.

#### 4.7. *Sc–Th–Rh–B*

Vandenberg and Matthias (1977) presented the crystal structure data of two alloys: Sc<sub>0.5</sub>Th<sub>0.5</sub>Rh<sub>4</sub>B<sub>4</sub> (ST CeCo<sub>4</sub>B<sub>4</sub>, SG *P4<sub>2</sub>/nmc*), lattice parameters  $a=5.322$ ,  $c=7.453$  Å, and Sc<sub>0.65</sub>Th<sub>0.35</sub>Rh<sub>4</sub>B<sub>4</sub> (ST CeCo<sub>4</sub>B<sub>4</sub>),  $a=5.317$ ,  $c=7.422$  Å. These data indicate the existence of the limited solid solution of substitution of Sc for Th in the ternary compound ThRh<sub>4</sub>B<sub>4</sub>.

#### 4.8. *Sc–Y(Lu)–Ir–Si*

Venturini et al. (1989) reported about the occurrence of continuous series of solid solutions between the isotypic ternary compounds Sc<sub>5</sub>Ir<sub>4</sub>Si<sub>10</sub>–Lu<sub>5</sub>Ir<sub>4</sub>Si<sub>10</sub> (ST Sc<sub>5</sub>Co<sub>4</sub>Si<sub>10</sub>) at 900°C. They investigated the variation of the lattice parameters with composition and the distribution of Sc and Lu atoms in the structure using four single crystals obtained from the solid solution region. The tetragonal lattice spacings of the solid solution Sc<sub>5–0</sub>Lu<sub>0–5</sub>Ir<sub>4</sub>Si<sub>10</sub> change within the limits  $a=12.314\text{--}12.475$  and  $c=4.076\text{--}4.171$  Å. A negative deviation from Vegard’s rule is observed. An isotypic single crystal Sc<sub>2.5</sub>Y<sub>2.5</sub>Ir<sub>4</sub>Si<sub>10</sub> with the lattice parameters  $a=12.3926$ ,  $c=4.1292$  Å has been investigated too. These data indicate the formation of a solid solution Sc<sub>5–x</sub>Y<sub>x</sub>Ir<sub>4</sub>Si<sub>10</sub> ( $0 \leq x \leq ?$ ). The alloys of the both four component systems are superconducting.

#### 4.9. *Sc–Dy–Ir–Si*

Another pseudobinary section Sc<sub>5</sub>Ir<sub>4</sub>Si<sub>10</sub>–Dy<sub>5</sub>Ir<sub>4</sub>Si<sub>10</sub> has been investigated by Ramakrishnan et al. (1992). These isotypic ternaries form a solid solution Sc<sub>5–x</sub>Dy<sub>x</sub>Ir<sub>4</sub>Si<sub>10</sub>

( $0 \leq x \leq 5$ ) with the linear dependence of both tetragonal lattice parameters  $a$  and  $c$  with  $x$ . Within this series superconductivity has been found for  $0 \leq x < 1.5$  and antiferromagnetic ordering for  $x > 1.5$ . The coexistence of superconductivity and magnetism is reported for  $x = 1.5$ . The superconducting transition temperature decreases rapidly with increasing  $x$  from  $T_c = 8.45$  K for  $x = 0$  down to about 4 K for the  $x = 1.5$  sample where the coexistence of superconductivity and magnetic order is observed. The magnetic ordering temperature  $T_N$  increases linearly from 3.5 to 5.0 K in the concentration range  $2 \leq x \leq 5$ . The temperature dependence of the resistivity of alloys is typical for a metal in the investigated temperature range up to 300 K.

#### 4.10. *Sc-Ni-C-B*, *Sc-Lu-Ni-C-B*

A superconducting transition was reported for metastable as-cast alloy of composition  $\text{ScNi}_2\text{B}_2\text{C}$  by Ku et al. (1994). The major phase has been indexed as the tetragonal  $\text{LuNi}_2\text{B}_2\text{C}$ -type structure (SG  $I4/mmm$ ) with the lattice parameters  $a = 3.34$ ,  $c = 10.2$  Å. Annealing of the alloy at 1050°C for 24 h led to the disappearance of the tetragonal phase and superconductivity.

The same authors reported on the pseudoquaternary system  $(\text{Lu}_{1-x}\text{Sc}_x)\text{Ni}_2\text{B}_2\text{C}$ . The unstable boundary is near the Sc-rich region ( $x > 0.5$ ). All the alloys are superconducting.

#### 4.11. *Sc-Y-Ge-Si*

Three alloys with the compositions  $\text{Sc}_{0.48}\text{Y}_{4.52}\text{Ge}_{0.29}\text{Si}_{2.71}$ ,  $\text{Sc}_{0.72}\text{Y}_{4.28}\text{Ge}_{0.43}\text{Si}_{2.57}$  and  $\text{Sc}_{4.25}\text{Y}_{0.75}\text{Ge}_{0.45}\text{Si}_{2.55}$  with the  $\text{Mn}_5\text{Si}_3$  type structure (SG  $P6_3/mcm$ ) have been prepared and examined by McCole and Kotroczo (1987). Taking into account the existence of isotypic binary compounds  $\text{Sc}_5\text{Si}_3$ ,  $\text{Sc}_5\text{Ge}_3$ ,  $\text{Y}_5\text{Si}_3$  and  $\text{Y}_5\text{Ge}_3$  it is possible to forecast the occurrence of continuous series of solid solutions between these binary phases with complete mutual substitution of Sc and Y and Si and Ge as well. Hydrogenation of the above mentioned alloys has been investigated.

#### 4.12. *Sc-Rh-Os-Si*

Braun and Segre (1980) investigated the phase composition at 1000°C of alloys within the section  $\text{Sc}_3\text{Os}_2\text{Si}_6$ – $\text{Sc}_3\text{Rh}_2\text{Si}_6$ . One of the components of this section, the compound of the tentative composition,  $\text{Sc}_3\text{Os}_2\text{Si}_6$ , is orthorhombic (see table 19, above). The second component, “ $\text{Sc}_3\text{Rh}_2\text{Si}_6$ ”, is a two-phase alloy containing the ternary compounds  $\text{Sc}_5\text{Rh}_4\text{Si}_{10}$  (ST  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ , see table 19) and  $\sim\text{Sc}_4\text{RhSi}_8$  (structure unknown, see table 19). The silicide  $\text{Sc}_3\text{Os}_2\text{Si}_6$  dissolves about 5.5 at.% Rh as deduced from the data presented in the table of the original paper. However, this value is not in agreement with the value given in the text, where a solubility of about 30 at.% Rh is mentioned. Variation of the lattice parameters vs. composition of the solid solution is not presented. Judging from the phase composition of the section, the  $\text{Sc}_3\text{Rh}_x\text{Os}_{2-x}\text{Si}_6$  solid solution is

in two-phase equilibrium with  $\text{Sc}_5\text{Rh}_4\text{Si}_6$  and in three-phase equilibrium with the phases  $\text{Sc}_5\text{Rh}_4\text{Si}_{10}$  and  $\sim\text{Sc}_4\text{RhSi}_8$ . The alloys of the section are superconducting.

#### 4.13. *Sc-Re-Ni-Si*

Zhao and Parthé (1989a) obtained a single crystal  $\text{Sc}_3(\text{Ni}_{0.96}\text{Re}_{0.04})_2\text{Si}_4$  and investigated its crystal structure: ST  $\text{Sc}_3\text{Ni}_2\text{Si}_4$ , SG *Pnma*,  $a = 11.679$ ,  $b = 3.985$ ,  $c = 11.991$  Å. These data are indicative of the formation of a limited solid solution of the substitution of Re for Ni in the ternary compound  $\text{Sc}_3\text{Ni}_2\text{Si}_4$ . However, these data are not complete and an additional investigation is necessary to define the limits of the solid solution.

#### 4.14. *Sc-Ca-Pt-P*

The only data about the Sc-Ca-Pt-P system concerns the  $\text{ScCa}_2\text{Pt}_7\text{P}_{\sim 3}$  quaternary compound, which has been reported by Lux et al. (1991). It is isotypic with  $\text{Eu}_2\text{Pt}_7\text{AlP}_{\sim 3}$ , SG *I4/mmm*,  $a = 4.038$ ,  $c = 27.027$ .

#### 4.15. *Sc-Y-Ti-Co*

The alloy with the composition  $\text{Sc}_{0.4}\text{Y}_{0.4}\text{Ti}_{0.2}\text{Co}_2$  is a single phase. It crystallizes in the cubic  $\text{MgCu}_2$ -type structure,  $a = 6.962$  Å. It was established by Burnashova et al. (1981) who also investigated the hydrogenation of the alloy. These data and the data about the binary compounds  $\text{ScCo}_2$ ,  $\text{YCo}_2$  and  $\text{TiCo}_2$  which also crystallize with the same structure indicate that there is possibly a complete solubility of these binary compounds, or a limited solubility of Ti in  $(\text{Y}_{1-x}\text{Sc}_x)\text{Co}_2$ .

### 5. Generalisation of the data on scandium metal systems and intermetallics

Phase diagrams give a fundamental insight into how two or more elements behave when they are combined in a system. An understanding of the interaction mechanism between the elements which results in different types of phase diagrams is one of the aims of physical and chemical investigations. The responsible physical parameters (factors) which determine this interaction are: the size, electrochemical, valence-electron, cohesive-energy and atomic number factors (Villars 1995). A review of the methods (usually semiempirical) proposed for the explanation and prediction of the constitution of phase diagrams, and the occurrence and crystal structure of intermediate compounds in the systems has been written by Villars (1995). The best semiempirical method for the calculation of the enthalpy of binary alloys based on the first three of the above-mentioned factors has been deduced by Miedema (1976). The prediction based on Miedema's model is in agreement with many experimental data. However, the attempts to apply this model to ternary systems failed. Villars (1995) introduced a new model using two additional factors (cohesive energy and atomic number) in order to explain the stability of ternary

compounds of proper structure types. Of course, each of these five factors used in Villars's model is related to the position of the corresponding element in the periodic table; however, it is impossible to replace them by only one.

Besides these semiempirical models, successful attempts have recently been undertaken in order to calculate the stability of binary, and in some cases ternary, compounds from first-principle band-structure calculations. As an example we want to mention the Vienna ab-initio simulation package VASP (see Kresse and Hafner 1993, 1994a and Kresse and Furthmüller 1996a,b). It performs an iterative solution of the Kohn–Sham equations of the local-density-functional (LDF) theory and allows one to use generalised gradient corrections. The electronic states are expanded in terms of plane waves, the electron–ion interaction is described in terms of ultrasoft pseudopotentials (see Vanderbilt 1990 and Kresse and Hafner 1994b). VASP allows for the calculations of the Hellmann–Feynman forces acting on the atoms and of the stresses on the unit cell. Hence the total energy may be optimised with respect to the volume and shape of the unit cell and of the positions of the atoms within the cell, with no other restrictions than those imposed by space-group symmetry. If such calculations are performed for several structure types it is possible to predict that structure which has the lowest equilibrium total energy, i.e. which is the stable one. Furthermore, it is possible to calculate the structural parameters (lattice parameters, atomic positions within the unit cell) from first principles, i.e. with no fitted parameters.

In any case a systematic analysis and generalisation of the available experimental data on the phase diagrams and compounds can contribute to improve the existing empirical or theoretical concepts. These regularities can also be used to predict the structure type and the properties of system not yet investigated. Below, some regularities and peculiarities of scandium metal systems and intermetallics found as a result of an analysis of the experimental data presented in sects. 2–4 are summarised.

### 5.1. *Regularities found in binary scandium phase diagrams*

All 65 investigated Sc–E binary phase diagrams can be divided into four types:

- (1) Systems with complete mutual solubility of components in liquid and solid (in at least one phase). Binary compounds do not occur. (E = 3A (except Eu, Yb, U), or 4A element).
- (2) Systems with immiscibility gap in liquid (monotectic). Binary compounds do not occur (E = 2A element or 3A element Eu, Yb, or U).
- (3) Systems with low or no mutual solubility of the components in solid (eutectic). Binary compounds do not occur (E = 5A, 6A element).
- (4) Systems with one or more binary compounds. Limited mutual solubility of the components in solid. (E = 2A, 7A–8A, 1B–6B element).

There are only two exceptions: the systems with U and Pu. Pu forms one binary compound with Sc, and in the Sc–U system appreciable limited mutual solubility of components in solid occurs. All rare earths (except Eu and Yb) and the 4A elements (Ti, Zr and Hf) are completely miscible with Sc in liquid and solid. It is necessary to indicate that Sc is the only element among the rare earths which forms continuous series

of solid solutions with other rare earths and with 4A elements. Zr and Hf, which have nearly the same atomic radius as Sc (1.602, 1.580 and 1.641 Å, respectively), usually form binary systems of the eutectic type with other rare earths, e.g. Zr–Y, Zr–Gd, Zr–Dy, Zr–Er, Hf–Y, Hf–Er (Massalski 1990).

Only Eu and Yb, among the rare earths, form immiscibility gaps with Sc in the liquid and solid. The difference in valence of these two rare earths and Sc is, perhaps, the main reason of this difference of interaction. The divalent state is more typical for Eu and Yb, whereas the other rare earths are usually trivalent. The same divalent state is characteristic for alkaline earths which are immiscible with Sc in the liquid and solid too. Therefore, it is possible to predict the same type of binary phase diagrams of Sc with alkaline metals. These elements are even more different from Sc in the valence state and other characteristics (melting temperature, electronegativity, etc.) than are the alkaline-earth metals.

All 5A–6A elements form eutectic-type binary systems with Sc with a low mutual solid solubility. With increasing melting temperature of the transition element the eutectic point shifts towards scandium.

The elements of all other groups form binary compounds with scandium. The number of binary compounds in each system is indicated in table 1 (above). Within each large period Sc forms the largest number of binary compounds with 8A and 3B elements. In the rows of the p-elements the number of binary compounds decreases with the increase of the group number of the element. The number of binary compounds changes inconsiderably with the increase of the period's number.

In the Sc–M (M=d element) binary systems, binary compounds of equiatomic composition ScM usually have the highest absolute values of enthalpy (Colinet and Pasturel 1994) and the highest melting temperature in the system. In the systems of scandium with p-elements the richest in scandium compound usually is the most thermodynamically stable one. Its composition is Sc<sub>5</sub>E<sub>3</sub> (E = Ga, Si, Ge, Sn, Pb), or ScE<sub>2</sub> (E = B), or ScE<sub>1-x</sub> (E = C). As was stated by Lukashenko et al. (1990a,b, 1991) scandium silicides and germanides are much more thermodynamically stable in comparison to silicides and germanides of other 3d elements. The thermodynamic properties are closer to those of the silicides and germanides of the lanthanides, than the 3d elements.

114 binary intermetallic compounds of scandium with definite crystal structure crystallize in 29 different compositions and belong to 56 structure types (table 28). The majority of them occur at constant compositions. In the cases when compounds have a variable composition their homogeneity ranges usually do not exceed 1 to 5 at.%. The compounds ScMg(β') and ScC<sub>1-x</sub> are the only two exceptions. The most common compositions of the scandium intermetallics occur at the stoichiometries ScE (30 compounds), ScE<sub>2</sub> (20 compounds), ScE<sub>3</sub> (9 compounds), Sc<sub>2</sub>E (8 compounds) and Sc<sub>5</sub>E<sub>3</sub> (8 compounds). Thus, more than 55% of binary scandium intermetallics (75 compounds among 134 known today) occur only at five simple stoichiometries out of 29 known to date. At these stoichiometries the compounds crystallize in different structure types depending on the position of element in the periodic table, as seen in table 28.

Table 28  
Stoichiometries and structure types of binary scandium intermetallics

Formula	Sc content (at.%)	Structure type	Pearson's symbol	Element (E) which forms the compound

Some binary compounds occur in two (ScFe<sub>2</sub>, ScNi<sub>5</sub>, Sc<sub>4</sub>C<sub>3</sub>, ScSi<sub>1.5</sub>, Sc<sub>3</sub>P<sub>2</sub>) or in three (Sc<sub>3</sub>As<sub>2</sub>) polymorphic modifications. The crystal structures of polymorphic forms are structurally related.

There is also a relation between the interval of stoichiometries (i.e. the composition range where the intermetallic phases are formed in the binary Sc-E system, see fig. 92) of binary compounds and the position of element in the periodic table. The widest intervals of compositions of the binary compounds with Sc display 8A and 3B elements (fig. 92). These are the elements which form the largest number of binary compounds with scandium. In the rows of d elements the least scandium content in compounds increases from 7A to 1B element and then sharply decreases for the 2B elements. A similar relation

Fig. 92. Intervals of stoichiometries of Sc-E binary compounds depending on the position of the E element in the periodic table.

is observed in the rows of p elements. The least scandium content sharply increases from 3B to 5B element and then decreases.

### 5.2. Regularities found in ternary scandium phase diagrams

Assuming that the data concerning a certain ternary system are complete if at least one isothermal section of the system has been investigated for  $\frac{3}{4}$  of the concentration region. There are about 70 such Sc-M-X ternary systems preferably with M = d, f element and X = B, Al, Ga, C, Si, Ge (table 13, above). The corresponding data are summarised in the tables 29 and 30. However, in such ternary systems additional ternary compounds which are stable over a limited temperature range may also exist. They, of course, will not be observed in investigation of the system at one temperature only, or if only a part of the system has been studied. In total, 420 ternary scandium intermetallic compounds have been synthesized. For 348 compounds (82.9%) the crystal structure was defined, and these compounds belong to 111 structure types.

The crystal structures have been investigated most completely for ternary compounds of the Sc-M-X systems with M = 3d, 4d, 5d, 4f element: with X = B, Al, Ga 102 compounds are known and with X = C, Si, Ge 178 compounds are known. Their compositions are given in figs. 93 and 94. Similarly as in the case of the binary systems, within the sequence of these ternary systems Sc-M-B, Sc-M-Al and Sc-M-Ga etc., within each period of the periodic table the number of ternary compounds usually increases with increasing atomic number of component M. The 8A-group elements therefore form the largest number of ternary compounds. Among the systems with 3B and 4B elements the ternary systems with boron differ considerably from those with aluminium and gallium. Also, the carbon systems behave different when compared with the Si and Ge systems. These systems differ by the number of ternary compounds occurring and by their compositions (tables 29 and 30, figs. 93 and 94). The ternary compounds ScMB<sub>2</sub> and ScMC<sub>2</sub> are exceptions in this sense. However, even in these cases the crystal structures of the ScMB<sub>2</sub> and ScMC<sub>2</sub> compounds are different from those of the ScMAl<sub>2</sub>, ScMSi<sub>2</sub> or ScMGe<sub>2</sub> compounds. In all other cases the stoichiometries of the ternary borides and carbides are different from

of their neighbours in the group. This difference exists also among their intermetallic compounds.

Intermetallic compounds of scandium with the 6B elements Se, Te and Po are different compared to all of the previously described scandium compounds. They crystallize in structures typical for oxides, sulphides and other ionic compounds (Al<sub>2</sub>MgO<sub>4</sub>, Fe<sub>2</sub>CaO<sub>4</sub>, ErCuS<sub>2</sub>, ErAgAs, NaCl structure types). In these structure types each atom is coordinated

by the atoms of the other elements, e.g. Sc atoms are surrounded by 6B atoms and vice versa. The coordination about a given atom is preferably octahedral and/or tetrahedral. At the same time these compounds show a metallic glide and a semimetal type of electrical conductivity (White and Dismukes 1965, Guittard et al. 1964, Hulliger and Vogt 1966, Julien-Pouzol et al. 1968, Julien-Pouzol and Guittard 1969). These compounds represent borderline cases between metallic and semimetal behaviours. On the other hand the atoms in the structures of typical intermetallic compounds are surrounded by both different atoms and identical atoms. The coordination number of atoms in intermetallics is rather high, from 6 to 20. The majority of scandium-containing phosphides and arsenides belong to the structure types which are typical for intermetallics, e.g.  $\text{TiNiSi}$ ,  $\text{ZrFe}_4\text{Si}_2$ ,  $\text{Zr}_2\text{Fe}_{12}\text{P}_7$ , etc.

A large number of ternary Sc–M–X compounds occur at stoichiometries which lie on three cross sections of a ternary phase diagram with the atomic ratios Sc : X = 1 : 1, Sc–M = 1 : 1, and M : X = 1 : 1, and on the section with Sc content of 33.3 at.% (see figs. 93 and 94). 55 ternary compounds with X = B, Al, Ga and 111 compounds with X = C, Si, Ge occur on these sections. Thus, more than half of the ternary compounds of 3B and 4B elements with known crystal structures lies on these four characteristic cross sections.

The analysis of the stoichiometries of 68 ternary scandium intermetallics determined in other systems (Sc–M–X, X = 5B, 6B element; Sc–X–X'; Sc–M–M') shows that 48 of them (~71%) also belong to these four sections. This means that about  $\frac{2}{3}$  of all scandium ternary intermetallics known today crystallize only on four appointed sections of phase diagrams and generally have simple stoichiometries.

This regularity had been discovered by Kotur and Bodak (1981) in a limited series of Sc–M–Si (M=3d element) systems. However, it seems to be characteristic for all ternary systems of scandium. As was mentioned by Villars (1995), simple stoichiometric ratios are in general preferred by intermetallic compounds.

A summary of the crystal structure data of the 463 (114 binary, 348 ternary and 1 quaternary) intermetallic compounds of scandium reviewed in this chapter are presented in Appendix A. They belong to 155 structure types, which are arranged in decreasing order according to the number of existing compounds. Structure types with the same number of representatives are arranged according to increasing number of atoms per unit cell. The number of the binary and ternary compounds representing each structure type is also given. Generalised data about the occurrence of ternary compounds of the various structure types in each group of systems is indicated too. The corresponding data for the binary systems are shown in table 28.

The largest number of ternary compounds are those with the simplest compositions: ScMX (a total of 61 compounds); ScMX<sub>2</sub> (19), ScM<sub>2</sub>X (18), ScM<sub>2</sub>X<sub>2</sub> (10), Sc<sub>3</sub>MX (9). A similar regularity has been found for binary scandium intermetallics (see sect. 5.1).

As one can see from figs. 93 and 94 more than 90% of all the intermetallic Sc compounds occur in the region of ternary system where the scandium content is less than ~50 at.% and which is limited by the sections Sc:M=1:1 with X content from 0 to 33.3 at.% and Sc:X=1:1 with the M content from 0 to 33.3 at.%.

A comparison of the investigated ternary systems of scandium with the related ternary systems of other rare-earth elements, which was presented in a Handbook by Bodak and Gladyshevsky (1985), reveals that especially for the light rare earths the ternary compounds often occur at larger RE content ( $\geq 50$  at.%). In this regard the scandium systems are closer to the systems of the d elements, especially those of the 4A group, Ti, Zr and Hf.

The majority of the scandium intermetallic structure types can also be found among intermetallic compounds of other rare earths as well as among intermetallics of the 4A elements (Villars and Calvert 1991). However, taking into consideration all 155 structure types of scandium intermetallics, from a crystal-chemical point of view, scandium appears to be closer to 4A elements, especially to Zr and Hf, rather than to the other rare earths.

The compounds of equiatomic composition ScMX, which occur frequently in ternary systems, belong to TiNiSi structure type and rarely to the ZrNiAl type structure. These two structure types are characteristic for intermetallics of d transition elements. The compounds of the other rare-earth elements prefer FCIPb, ZrNiAl and AlB<sub>2</sub> structure types (Villars and Calvert 1991). The RM<sub>2</sub>X<sub>2</sub> compounds belong to one of the most frequently occurring structure types, namely CeGa<sub>2</sub>Al<sub>2</sub> (or ThCr<sub>2</sub>Si<sub>2</sub>) and La<sub>2</sub>O<sub>2</sub>S. We note that among ScM<sub>2</sub>X<sub>2</sub> compounds only three representatives are known with the CeGa<sub>2</sub>Al<sub>2</sub> type structure, but none with the La<sub>2</sub>O<sub>2</sub>S type structure. The ScFe<sub>2</sub>Si<sub>2</sub> compound is isotypic with HfFe<sub>2</sub>Si<sub>2</sub>, which does not occur among other rare-earth intermetallics. Another typical stoichiometric ratio of the rare-earth compounds is RMX<sub>2</sub>, however, scandium is the only rare-earth element which does not form phases with CeNiSi<sub>2</sub> structure type, but instead forms compounds of the

ZrCrSi<sub>2</sub> (or TiMnSi<sub>2</sub>) type. Scandium is the only rare earth which forms compounds with ZrSi<sub>2</sub>, Zr<sub>4</sub>Co<sub>4</sub>Ge<sub>7</sub>, Zr<sub>2</sub>Cr<sub>4</sub>Si<sub>5</sub> structure types, which are frequently observed among intermetallics of d elements. There are no d-element compounds of the ScNiSi<sub>3</sub>, Sc<sub>2</sub>Fe<sub>3</sub>Si<sub>5</sub>, Sc<sub>2</sub>Co<sub>3</sub>Si<sub>5</sub>, Sc<sub>3</sub>Ni<sub>11</sub>Si<sub>4</sub> structure types, however, a lot of them are found among rare-earth intermetallics. These are examples confirming the unique position of scandium within the family of rare-earth elements. To some extent Sc is the linking element between the rare earths and the d elements.

### 5.3. Atomic size factor and its influence on the nature of scandium intermetallics

The constant compositions of ternary compounds and the absence of solid solutions on the basis of binary compounds are other characteristic features of scandium systems (with the exception of the systems Sc–M–Ga with M = rare earth or 4A element). However, in some systems solid solutions of phases with narrow homogeneity regions occur. Sometimes a substitution of Sc and M atoms occurs and sometimes the M and the X atoms are mutually substituted. There is no doubt that the atomic size factor has a dominating influence on the formation of solid solutions and their nature (solid solutions of substitution, of inclusion or of subtraction of atoms). Examples of solid solutions of substitution are presented in table 31. It is interesting to note that all ternary compounds which form such solid solutions crystallize in structures characteristic for binary compounds.

Julien-Pouzol et al. (1968) found that in the Sc–Cu–Se ternary system a solid solution with the limit compositions ScCuSe<sub>2</sub>–Sc<sub>0.67</sub>Cu<sub>2</sub>Se<sub>2</sub> exists due to the subtraction of a

Table 31  
Mutually substituted atoms in the structures of ternary compounds of the Sc–M–X systems

Mutually substituted atoms		Ratio of atomic radii		Structure type of ternary compound

Fig. 95. Projection of the structure  $Mn_5Si_3$  along 001. CP of atoms: (a) M1 occupying 6(g) site with CN=15; (b) M2 occupying 4(f) site with CN=14; (c) Si occupying another 6(g) site with CN=11. Empty octahedra  $[M1_6]$  are labelled (d).

fraction of Sc atoms and the addition of Cu atoms in different atomic sites. Other examples of solid solutions of addition or subtraction are observed in other ternary systems, such as  $Sc-M-X$  and  $Sc-X'-X$  ( $X=B, C$ ) where small boron or carbon atoms are added into the octahedral cavities of the  $AuCu_3$  type structure, revealing the formation of perovskite-type ternary compounds  $ScM_3B_{1-x}$ ,  $Sc_3X'B_{1-x}$ ,  $ScM_3C_x$  and  $Sc_3X'C_x$  (Holleck 1977).

The binary compounds  $Sc_5Si_3$  and  $Sc_5Ge_3$  can be distinguished among other binary scandium intermetallics. Both crystallize in the  $Mn_5Si_3$  structure type (hP16; SG  $P6_3/mcm$ ), which is a common structure type of intermetallics. Its projection along the 001 direction is presented in fig. 95. The  $A_5B_3$  compounds with the  $Mn_5Si_3$  structure type are formed by 3A–8A elements as the A constituent with the 3B–5B elements as the B constituent (Villars and Calvert 1991). The ratios of atomic radii ( $r_A/r_B$ ) for these compounds are observed over a wide interval, from 0.83 for  $Ti_5Pb_3$  to 1.35 for  $Y_5Si_3$ . This is, perhaps, the main reason for the existence of substitutional solid solutions of Sc and the majority of d and f elements in  $Sc_5Si_3$  and  $Sc_5Ge_3$  over wide compositional intervals up to formation of continuous series of solid solutions.

Usually the lattice parameters of these solid solutions display a nonlinear dependence on the composition. These data are available in numerous papers, see e.g. Kotur and Parasiuk (1994), Kotur (1986, 1991), Kotur and Mokra (1994). The nature of mutual substitution of Sc and other atoms has been investigated by Kotur and Parasiuk (1994) for the  $Sc_2Er_3Si_3$  and  $Sc_3Er_2Si_3$  continuous series of solid solutions, i.e.  $Sc_xEr_{5-x}Si_3$ . Scandium and erbium atoms substitute for each other statistically in two crystallographic sites 6(g) and 4(f) of the structure within the solid solution. Contrary to these data the investigation of the  $ScV_4Si_3$  single crystal revealed a partial ordering of Sc and V atoms in the structure (Kotur et al. 1983a). V atoms occupy the 4(f) site with CN=14, and the rest of the V atoms together with Sc atoms occupy the 6(g) site with the higher CN=15. The solubility of V in  $Sc_5Si_3$  at 800°C does not exceed 1 at.%. The ternary compound  $Sc_2V_3Si_3$  with practically a constant composition at 800°C isotypic with  $Mn_5Si_3$  has been found in the system. The reason seems to be the considerably large difference in the atomic sizes of Sc and V in comparison to the sizes of Sc and Er atoms.

The  $Mn_5Si_3$  structure type can be also stabilized in systems by the inclusion of small C, N, O or B atoms into the empty octahedra  $[\square M1_6]$ . Columns of these octahedra are stretched along  $6_3$  axes in the structure (fig. 95). Kotroczo and McColm (1987) and McColm and Kotroczo (1987) investigated hydrogen sorption into the  $[\square R_6]$  octahedra of  $Sc_5Si_3$ ,  $Sc_5Ge_3$  binary compounds and of three- and four-component alloys of solid solutions based on these binary phases. As a result the hydrides of the  $Y_{5-a}Sc_aSi_3H_{2.5}$ ,  $Y_{5-a}Sc_aSi_3H_{1.5}$ ,  $Y_{5-a}Sc_aSi_{3-b}Ge_bH_{2.5}$  and  $Y_{5-a}Sc_aSi_{3-b}Ge_bH_{1.5}$  compositions have been obtained.

Venturini et al. (1989) investigated the nature of solid solutions  $(Lu_{1-x}Sc_x)_5Ir_4Si_{10}$  and  $(Y_{1-x}Sc_x)_5Ir_4Si_{10}$  which occur between isotypic ternary compounds  $R_5Ir_4Si_{10}$  (ST  $Sc_5Co_4Si_{10}$ ). The lattice parameters of the  $(Lu_{1-x}Sc_x)_5Ir_4Si_{10}$  solution exhibit a negative deviation from Vegard's rule within its homogeneity range. Single-crystal investigations reveal that the Lu and Sc atoms statistically occupy three R atomic sites in this structure. A statistical substitution of Sc by the heavy R atoms is commonly observed in the systems, however, such admixture is rare in ternaries with light R elements. As a result, ternary compounds with ordered or partially ordered structures in the rare-earth sites occur. This is also the result of the influence of the atomic size factor. The number of compounds in the Sc-R-Si systems decreases remarkably when passing from systems with light rare earths (Sc-Ce-Si, eight ternary compounds; Sc-Nd-Si, five compounds) towards heavy rare-earth systems (Sc-Dy-Si, two compounds; Sc-Lu-Si, no compounds known) (Kotur 1995), however, simultaneously the possibility for a mutual substitution of Sc and R atoms increases. For example, the highest solubility of Sc and R at 600°C in the binary phases in the Sc-R-Si systems is as follows: 6 at.% (R = Ce), 13 at.% (R = Sm), continuous solid solution (R = Dy, Lu). The main reason for this is the decrease of the R atomic radius from Ce towards Lu due to the lanthanide contraction.

Among the d elements only Ti, Zr and Hf can form solid solutions of substitution with Sc up to continuous series of solid solutions. Such solid solutions are observed in binary as well as in ternary systems. The atomic size factor is the main reason for these phenomena.

However, the influence of other factors (beside the atomic size factor) on the interaction of the elements is obvious when comparing the ternary systems R-Sc-Si and R-Zr(Hf)-Si. These data are presented in table 32. Although the atomic sizes of Sc, Zr and Hf are nearly the same the interaction of 4A elements with the rare earths in binary and ternary systems is different from that in the corresponding systems of scandium with the rare earths. It does not depend on whether R is a light or heavy rare earth. Sc is completely miscible with Ce and Y in binary systems while Y-Zr and Y-Hf systems are of eutectic type with low mutual solubility of the components in the solid. In the Ce-Hf system an immiscibility gap in the liquid and solid occurs (Massalski 1990). The same type of behaviour is predicted for the Ce-Zr binary system.

Thus, the position of scandium among the family of rare earths is to some extent unique. Sometimes it behaves as a typical R element (e.g. showing a complete miscibility, except with Eu and Yb), however in other cases it exhibits a behaviour more similar to the d elements (e.g. displaying complete miscibility with them too, namely with Zr and Hf).

Table 32  
Comparison of characteristics of R–M–Si (M = Sc, Zr, Hf) ternary systems

Characteristic	Systems					
	Y–M–Si			Ce–M–Si		
	Sc	Zr	Hf	Sc	Zr	Hf
Number of ternary compounds	1	1	0	8	3	0
Occurrence of continuous series of solid solutions	+	–	–	–	–	–

This peculiarity of scandium is also observed in ternary systems. It is a linking element between the rare earth and the d transition elements. Zr, Hf and the heavy rare earths are the elements with which scandium forms statistical mixtures of atoms, up to a complete mutual substitution in the structures. With other elements scandium occupies regular atomic positions in the structures and forms, as usual, ternary compounds of constant composition.

5.4. *Relations between compositions and crystal structures of scandium intermetallics*

There are 155 known structure types of scandium intermetallics having a different number of representatives from only 1 up to 20 (see Appendix A). More than half of the ternary compounds studied up to now (207, ~60%) belong to only 25 structure types with representatives from 5 to 20. Of these 25, 21 structure types also occur in binary compounds or are superstructures to corresponding binary prototypes. In the group of 27 most frequently occurring structure types of scandium intermetallics there are 9 structure types, namely MgZn<sub>2</sub>, CsCl, AlB<sub>2</sub>, MgCu<sub>2</sub>, Mn<sub>5</sub>Si<sub>3</sub>, AuCu<sub>3</sub>, CrB, ZrSi<sub>2</sub>, Ti<sub>2</sub>Ni, observed for 52 binary scandium intermetallics (46%) of 5 stoichiometric compositions (see sect. 5.1). As is seen from Pearson's symbol, the compounds with simple structures and small numbers of atoms in the unit cell (from 2 up to 20) and with high symmetry (not lower than orthorhombic) occur most frequently. Only 5 structure types among 155 types are monoclinic. 28 and 77 structure types have, respectively, only two or one representatives among scandium intermetallics. Their compositions and crystal structures usually are not simple. The highest number of atoms (408) in a unit cell has Mg<sub>44</sub>Rh<sub>7</sub> type structure.

The formation of comparatively simple, highly symmetrical crystal structures is not only characteristic for scandium intermetallics, but is typical for intermetallics in general,

Table 33  
Types of relations between structure types of scandium intermetallics

Type of relation	Operation of transition from initial to resulting type	Examples of structure types	
		Initial	Resulting
I. Positions of all atoms are the same	I. Ordered substitution of atomic positions by different atoms ( $\rightarrow$ superstructure)	Sm <sub>3</sub> Ge <sub>4</sub> La <sub>2</sub> Sb CaIn <sub>2</sub>	Ce <sub>2</sub> Sc <sub>3</sub> Si <sub>4</sub> Mo <sub>2</sub> FeB <sub>2</sub> ScAuSi
II. Positions of all atoms are roughly the same	II. Distortion (internal and/or external)	CaIn <sub>2</sub> CeCo <sub>3</sub> B <sub>2</sub>	KHg <sub>2</sub> ErIr <sub>3</sub> B <sub>2</sub>
III. Positions of part of atoms are the same	IIIa. Multiple substitution of atoms (1 $\rightarrow$ 2)	FCIPb CaCu <sub>5</sub>	ScCoC <sub>2</sub> ThMn <sub>12</sub>
	IIIb. Addition (subtraction) of atoms	AuCu <sub>3</sub> NaCl	CaTiO <sub>3</sub> Sc <sub>2</sub> S <sub>3</sub>
	IIIc. Redistribution of part of atoms and cavities	MgAgAs	MgLiAl
	IIId. Redistribution of atoms	Th <sub>2</sub> Zn <sub>17</sub>	Th <sub>2</sub> Ni <sub>17</sub>
IV. Fragments of both structures are the same	IV. Different stacking types of fragments (homeotypic rows or structures)	MgZn <sub>2</sub> AlB <sub>2</sub> TiNiSi	MgCu <sub>2</sub> $\alpha$ ThSi <sub>2</sub> ZrNiAl
V. Roughly the same fragments, but different ratios of them	Va. One-dimensional stacking of fragments	(CaCu <sub>5</sub> , Zr <sub>4</sub> Al <sub>3</sub> ) (CeGa <sub>2</sub> Al <sub>2</sub> , $\alpha$ Po)	HfFe <sub>6</sub> Ge <sub>6</sub> ScNi <sub>2</sub> Si <sub>3</sub>
	Vb. Two-dimensional stacking of fragments	(CrB, TiNiSi)	Sc <sub>2</sub> CoSi <sub>2</sub> , Sc <sub>3</sub> NiSi <sub>3</sub>
	Vc. Three-dimensional stacking of fragments	( $\alpha$ Fe, AlB <sub>2</sub> , FeB) ( $\alpha$ Fe, AlB <sub>2</sub> )	Ce <sub>2</sub> Sc <sub>3</sub> Si <sub>4</sub> Th <sub>7</sub> Fe <sub>3</sub>

as was stated by Villars (1995). This is due to the metallic bonding prevailing in intermetallics. Structures of higher complexity appear frequently in compounds with covalent-type bonding.

Different relations within the various structure types are known to exist in intermetallic compounds in general, and this is also valid in the case of scandium intermetallics. These relations are summarised in table 33 and illustrated using examples of scandium structure types. The relations between structure types of intermetallic compounds were treated in more details by Kripyakevich (1977). He proposed systematics of the structure types of intermetallic and other related compounds, which is based on the analysis of the coordination surroundings (CN and shape of CP) of the smallest atoms in the structure.

As already mentioned, ternary scandium intermetallics often crystallize in structure types which are superstructures to binary prototypes (table 33, Appendix A). It seems convenient to us to select structure types among them which occur in large groups of elements and their combinations, see table 34. These structure types as well as their binary prototypes are frequently observed among all intermetallics having up to hundreds of known representatives. The atomic size factor has a dominant influence on distribution of atoms in ternary phases. The largest atoms in the structure normally occupy atomic

sites with the largest CN and the smallest atoms occupy positions with the smallest CN. Scandium atoms are often the largest ones in the structures, with the exception of other R elements. In those cases scandium atoms occupy atomic sites with a medium value of CN. Ternary aluminides, gallides, silicides and germanides sometimes form isotypic compounds which belong to the same superstructure types, for e.g.  $ZrNiAl$ ,  $Mg_6Cu_{16}Si_7$  (see Appendix A). The Al and Ga atoms in these structures are usually larger than transition element atoms. Therefore they occupy opposite sites in comparison with the isotypic ternary scandium transition element silicides and germanides in which Si and Ge atoms are usually the smallest ones. Some examples are presented in table 35. Sometimes it causes the change of stoichiometry of compounds:  $Sc_6Co_{16}Si_7 \rightarrow Sc_6Co_7Ga_{16}$ ,  $Ce_2Sc_3Ge_4 \rightarrow V_3Sc_2Ge_4$ ,  $ScCo_3C \rightarrow SnSc_3B$ .

$Ho_{11}Ge_{10}$  is the binary prototype of differently ordered or partially ordered ternary structures (superstructures)  $Sc_7Cr_{4+x}Si_{10-x}$  (Kotur et al. 1985a),  $Sc_7Re_{4-x}Si_{10+x}$  (Zhao et al. 1988) and  $Sc_{11}Al_2Ge_8$  (Zhao and Parthé 1991) and  $Sc_6Yb_5Ge_{10}$  (Kotur et al. 1996b). A detailed analysis of these structures has been reported in the latter paper. The stoichiometries of these phases vary in wide limits as the result of substitution of different R and X atomic sites by d elements (Cr, Mn), and by statistical mixtures of d and p elements (Re, Si). Other ternary substitution variants of the  $Ho_{11}Ge_{10}$  binary prototype are also possible. It can be expected that in the near future the  $Ho_{11}Ge_{10}$  structure type may belong to the group of most frequently occurring structure types of intermetallic compounds.

The structures of many binary and ternary scandium borides and carbides may be deduced from other structure types by a multiple substitution of larger atoms by B–B or C–C pairs or by the inclusion of B or C atoms into the cavities of the parent structure types. The same is valid for the structures of scandium intermetallics with the 6B elements. The  $Ti_7S_{12}$ , NiAs, ErAgSe<sub>2</sub> and  $Al_2MgO_4$  structure types can be obtained by an inclusion of cations of metals into the octahedral and tetrahedral cavities of different packings (usually close ones) of 6B anions. Frequently the inclusion of atoms causes a distortion of the parent close-packed structure.

A large group of scandium intermetallics contain fragments of simpler structure types connected in different manners. Some of these hybrid structures contain fragments of two, three or even more structure types. Usually the initial fragments are distorted during their connection in the hybrid structure. Such distortions are minimal in linear hybrid structures. The dimensions of initial fragments, their number and the manner of mutual connection determine the dimensions and the symmetry of the resulting hybrid structure. Often fragments of the following structure types:  $\alpha\text{Po}$  (empty cube),  $\alpha\text{Fe}$  (body-centered cube),  $\text{AlB}_2$  (body-centered trigonal prism) and  $\text{BaAl}_4$  (body-centered tetragonal antiprism), are observed as the initial fragments for hybrid structures. Besides these, atomic groups (clusters) such as octahedron- and icosahedron-shaped are found as the structure fragments. The initial fragments can be eliminated from the parent structures along the axes of the unit cells or eliminated randomly in comparison to these axes. Substitutions of atomic positions of the same structure fragments by different atoms with different sizes cause distortions of the same fragments in different structures. In the following discussion possible distortions of structure fragments will not be taken into consideration and we will use the names of ideal clusters.

While analysing the compositions of scandium intermetallic compounds we hinted at the regularity of occurrence of large numbers of compounds on some characteristic cross sections of phase diagrams (see figs. 93 and 94). The crystal structures of these compounds which are in two-phase equilibrium with each other are related and contain one or more mutual fragments, but in different ratios. For example, on the cross-section  $\text{Sc}:X=1:1$  of the ternary systems  $\text{Sc}-M-X$  ( $M=\text{Fe}, \text{Co}, \text{Ni}$ ;  $X=\text{Si}, \text{Ge}$ ) the following ternary compounds occur:  $\text{ScMX}$  (ST  $\text{TiNiSi}$ ),  $\text{Sc}_3\text{M}_2\text{X}_3$  (ST  $\text{Hf}_3\text{Ni}_2\text{Si}_3$ ),  $\text{Sc}_2\text{MX}_2$  (ST  $\text{Sc}_2\text{CoSi}_2$ ),  $\text{Sc}_3\text{MX}_3$  (ST  $\text{Sc}_3\text{NiSi}_3$ ), and  $\text{ScX}$  (ST  $\text{CrB}$ ). These compounds form an interesting series of structures  $\text{ScMX} \rightarrow \text{Sc}_3\text{M}_2\text{X}_3 \rightarrow \text{Sc}_2\text{MX}_2 \rightarrow \text{Sc}_3\text{MX}_3 \rightarrow \text{ScX}$  (Gladyshevsky and Kotur 1978, Kotur and Gladyshevsky 1983). As can be seen from fig. 96 three intermediate members of this series contain fragments of the outer two,  $\text{ScMX}$  and  $\text{ScX}$ . In this series the  $\text{Sc}:X$  ratio remains the same, 1:1, however, the decrease of the number of the  $M$  atoms cause the decrease and finally the disappearing of the  $\text{TiNiSi}$ -type fragments. The number of  $\text{CrB}$ -type fragments increases from the  $\text{Sc}_3\text{M}_2\text{X}_3$  structure towards  $\text{ScX}$ . Thus,  $\text{TiNiSi}$  and  $\text{CrB}$  are the parent structure types of the homological series of structures with three known members. It is possible to predict the existence of other members in this series and construct their hypothetical structures. In particular, if we add one unit cell of  $\text{ScSi}$  along the  $c$  direction in the  $\text{Sc}_3\text{NiSi}_3$  (I) structure, we obtain a structure of the same symmetry (SG  $C2/m$ ) represented by the formula  $\text{Sc}_4\text{NiSi}_4$  (II). The monoclinic unit cell of this hypothetical structure will have the following dimensions:  $a(\text{II}) \approx a(\text{I}) \approx 10 \text{ \AA}$ ,  $b(\text{II}) \approx b(\text{I}) \approx 4 \text{ \AA}$ ,  $c(\text{II}) \approx c(\text{I}) + c(\text{ScSi}) \approx 16.5 \text{ \AA}$ ,  $\beta \approx 95-98^\circ$  (Kotur and Gladyshevsky 1983). Taking into account that the  $\text{CrB}$ -type structure is the linear hybrid structure of  $\text{AlB}_2$  and  $\alpha\text{Fe}$  types, the structures of above discussed homological series are thus two-dimensional hybrids of three structure types, namely  $\alpha\text{Fe}$ ,  $\text{AlB}_2$  and  $\text{TiNiSi}$ .

The germanide  $\text{Sc}_9\text{Ni}_5\text{Ge}_8$  occurs very close to the  $\text{Sc}:X=1:1$  cross-section. Its structure has been determined by Andrusyak et al. (1989), and appeared to be a more

Fig. 96. Relations between the structure types TiNiSi (ScCoSi),  $\text{Hf}_3\text{Ni}_2\text{Si}_3$  ( $\text{Sc}_3\text{Co}_2\text{Si}_3$ ),  $\text{Sc}_2\text{CoSi}_2$ ,  $\text{Sc}_3\text{NiSi}_3$  and CrB (ScSi). The structures are presented in the projections along 010 or 100. Unit cells and structure fragments are indicated by dashed and solid lines respectively.

complicated two-dimensional hybrid of four structure types, namely  $\alpha\text{Fe}$ ,  $\text{AlB}_2$ , TiNiSi and  $\text{Mo}_2\text{NiB}_2$  (fig. 97).

The structure of ScNiSi of the TiNiSi type can be presented as consisting of infinite zig-zag walls of trigonal prisms  $[\text{XM}_4\text{X}_2]$  (see Kotur and Sikirica 1982b). Also the structure of  $\text{Sc}_3\text{Ni}_4\text{Si}_4$  (ST  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$ ) contains trigonal prisms and is in equilibrium with ScNiSi. In the Sc–Cu–Si ternary system the compound  $\text{Sc}_3\text{Cu}_4\text{Si}_4$  (ST  $\text{Gd}_6\text{Cu}_8\text{Ge}_8$ ) is in equilibria with ScCuSi (r) (ST TiNiSi) and ScCuSi (h) (ST ZrNiAl). The structure of the latter compound is also built of trigonal prisms. As is seen from the stoichiometries of the ternary compounds presented, they occur on the cross-sections  $\text{M}:\text{X} = 1:1$  and therefore their crystal structures are related and contain mutual fragments.

In the numerous ternary R–M–X systems on the cross-sections  $\text{R}:\text{M} = 1:1$  there are ternary compounds of the compositions  $\text{RMX}_2$  and  $\text{RMX}_3$ , which belong to the structure types of  $\text{CeNiSi}_2$  and  $\text{ScNiSi}_3$  (Gladyshevsky and Bodak 1982). As follows from fig. 98, the structures of these compounds are related and contain mutual fragments of  $\text{AlB}_2$  and  $\text{CeGa}_2\text{Al}_2$  (superstructure to  $\text{BaAl}_4$ ) types. Although there are no data to date for any scandium compound of  $\text{CeNiSi}_2$  type, the silicide ScNiSi<sub>3</sub> contains its fragments in its structure. There are relations between the structures of compounds occurring on other cross-sections, e.g.  $\text{Sc}:\text{M} = 1:2$ . The compounds  $\text{ScNi}_2\text{Si}_3$  (ST  $\text{ScNi}_2\text{Si}_3$ ) and  $\text{ScNi}_2\text{Si}_2$  (ST  $\text{CeGa}_2\text{Al}_2$ ) are in equilibrium with each other and contain a mutual structure fragment

Fig. 97. Connection of fragments (indicated by solid lines) of  $\alpha$ -Fe,  $AlB_2$ ,  $Mo_2NiB_2$  and  $TiNiSi$  structure types in the structure of  $Sc_9Ni_2Ge_8$ . Unit cells are indicated by dashed lines. The structures are presented in the projections along 001 or 010.

(fig. 98). The structures  $ScNiSi_3$ ,  $ScNi_2Si_3$  and  $CeNiSi_2$  presented in fig. 98 are linear hybrid structures.

The linear hybrids of two structure types,  $CeGa_2Al_2$  and  $\alpha$ Fe, are ternary carbides  $Sc_3CoC_4$  and  $ScCoC_2$ , which are in equilibrium with each other and occur on the isoconcentrate of 50 at.% C in the Sc–Co–C system.

The examples, discussed above, show that ternary compounds which are in equilibrium with each other are related with respect to their crystal structure. These compounds contain at least one mutual fragment or atomic cluster. Sometimes they form homologous series of structures. This fact can be used for the investigation of compounds with unknown crystal structure. However, to date there are a number of powerful program packages available for the determination of crystal structures by direct methods. However, the application of direct methods for structure determination using powder X-ray data is sometimes not successful, especially for complex structures. In such cases the knowledge of structure relations between compounds which are in equilibria becomes very useful if the structures of some of them are known.

We used such an approach for determination of the crystal structure of  $ScFe_6Ge_5$  (Kotur 1995). In the ternary systems Sc–Mn–Ge and Sc–Fe–Ge on the cross-sections Sc:Mn(Fe)=1:6 the compounds  $ScM_6Ge_6$  (M=Mn, Fe),  $ScFe_6Ge_5$  and  $ScM_6Ge_4$  (M=Mn, Fe) exist. The germanides  $ScM_6Ge_6$  and  $ScM_6Ge_4$  belong to the structure types  $HfFe_6Ge_6$  (Olenych et al. 1981) and  $ZrFe_6Ge_4$  (Olenych 1989), respectively. The structure of the  $HfFe_6Ge_6$  type can be deduced from the  $CaCu_5$  type by a multiple substitution of the pair of X–X atoms for the M atoms in every second layer (fig. 99). The structure of

Fig. 98. Relations between structures  $\text{ScNiSi}_3$ ,  $\text{CeNiSi}_2$  occurring on the cross-sections  $R:M=1:1$  and  $\text{ScNi}_2\text{Si}_3$ ,  $\text{ScNi}_2\text{Si}_2$  (ST  $\text{CeGa}_2\text{Al}_2$ ) occurring on the cross-sections  $R:M=1:2$ . The structures are presented in the projections along 100 or 010. Unit cells are indicated by dashed lines. Fragments of the structures: (I)  $\alpha\text{Po}$ , (II)  $\text{CeGa}_2\text{Al}_2$ , (III)  $\text{AlB}_2$ , (IV)  $\text{CeNiSi}_2$ .

$\text{HfFe}_6\text{Ge}_6$  (IV) is also a linear hybrid of the  $\text{CaCu}_5$  (I) and the  $\text{Zr}_4\text{Al}_3$  (II) types (fig. 99), whereas the structure of the  $\text{ZrFe}_6\text{Ge}_4$  (V) type is a linear hybrid of the  $\text{CaCu}_5$  (I) and  $\text{Fe}_3\text{Sn}_2$  (III) types (fig. 99). The  $\text{ZrFe}_6\text{Ge}_4$  type structure can also be treated as resulting from an inclusion of  $\text{R}(\text{Sc})$  atoms into the  $\text{Fe}_3\text{Sn}_2$  structure (fig. 99).

Expecting genetic relations between the structures of  $\text{ScFe}_6\text{Ge}_5$  and  $\text{ScFe}_6\text{Ge}_6$  (IV) and  $\text{ScFe}_6\text{Ge}_4$  (V), with which the first one are in equilibria, Kotur (1995) deduced a theoretical model for the crystal structure of  $\text{ScFe}_6\text{Ge}_5$  as a linear hybrid of the fragments IV and V. This model, containing 72 atoms in the unit cell, is presented in fig. 99. The dimensions of the fragments IV and V, their quantities, 3 + 3, and symmetry allowed one to determine roughly the unit cell dimensions and the symmetry:  $SG R\bar{3}m$ ,  $a \approx 5 \text{ \AA}$ ,  $c \approx 44 \text{ \AA}$ . This theoretically predicted structure has been confirmed experimentally by X-ray powder diffraction data; the refined lattice parameters are:  $a = 5.063(1) \text{ \AA}$ ,  $c = 44.11(1) \text{ \AA}$  (Kotur 1995).

Fig. 99. Relations of the structures  $\text{CaCu}_5$ ,  $\text{ScFe}_6\text{Ge}_6$  (ST  $\text{HfFe}_6\text{Ge}_6$ ),  $\text{Zr}_4\text{Al}_3$ ,  $\text{Fe}_3\text{Sn}_2$ ,  $\text{ScFe}_6\text{Ge}_4$  (ST  $\text{ZrFe}_6\text{Ge}_4$ ) and  $\text{ScFe}_6\text{Ge}_5$ . The structures are presented in the projections on the plane of the large diagonal of the hexagonal basis. Unit cells are indicated by dashed lines. Fragments of the structures: (I)  $\text{CaCu}_5$ , (II)  $\text{Zr}_4\text{Al}_3$ , (III)  $\text{Fe}_3\text{Sn}_2$ , (IV)  $\text{ScFe}_6\text{Ge}_6$ , (V)  $\text{ScFe}_6\text{Ge}_4$ .

The change of compositions of compounds is connected with the changes of coordination surroundings of atoms. Kotur (1995) performed a crystal structure analysis of all known structure types of scandium intermetallics based on the classification presented by Kripyakevich (1977). The structure types have been classified on the basis of the CN and the shape of the CP of the smallest atoms in the structure. In some cases the X atoms are the smallest in the structure but sometimes the M atoms are the smallest, especially if M is a d element. It was found that the compounds with a high M content (>50 at.%) and a low X content (<30 at.%) frequently have the CN 12 and the CP of icosahedra and cubooctahedra for the smallest atoms. The compounds of the central part of ternary systems with Sc content 15 up to 30 at.% and the X content between 30 and 50 at.% have CN 8 (+1 or 2) and a CP of tetragonal antiprism for the smallest atoms. For high X (>50 at.%) and Sc (>30 at.%) content the compounds are characterised by a trigonal prismatic coordination of the smallest atoms [CN 6 (+1, 2 or 3)]. At high Sc content binary compounds have icosahedral coordination of the smallest atoms. These regularities are invalid in the systems of X elements (B, C, As), with a pronounced nonmetal character. Scandium intermetallics with these elements have, as usual, trigonal prismatic, octahedral (CN 6) and tetrahedral (CN 4) coordination of the X atoms.

Fig. 100. Coordination polyhedra of atoms: (a) cubooctahedron; (b) icosahedron with two tetragonal planes; (c, d) normal icosahedron in two projections; (e) trigonal prism with three additional atoms; (f) tetragonal antiprism with one additional atom; (g, i, k) octahedron in different projections; (h) trigonal prism with one additional atom. The arrows near atoms show the approximate direction of their shifts, which cause the transformation of this CP into the neighbouring one, indicated by a long arrow (for additional explanation see text).

Figure 100 represents the transformations of the CP of atoms observed in the structures: cubooctahedron (CN 12)  $\rightarrow$  icosahedron with two quadrangular planes (CN 12)  $\rightarrow$  normal icosahedron (CN 12)  $\rightarrow$  trigonal prism with additional atoms [CN 6 (+3)]  $\rightarrow$  tetragonal antiprism with additional atom [CN 8 (+1)]  $\rightarrow$  octahedron (CN 6) and also the transformation of trigonal prism with additional atom [CN 6 (+1)]  $\rightarrow$  octahedron (CN 6). Numerous examples of these CP can be found in the original papers for the structures of intermetallics. Namely, CP (a) from fig. 100 is observed for the atoms of the  $\text{AuCu}_3$  ST,  $[\text{AuCu}_{12}]$  and  $[\text{CuAu}_4\text{Cu}_8]$  (Kripyakevich 1977). Slightly distorted cubooctahedrons  $[\text{ScRh}_6\text{Ge}_6]$  exist in the  $\text{Sc}_4\text{Rh}_7\text{Ge}_6$  structure (ST  $\text{U}_4\text{Re}_7\text{Si}_6$ , Engel et al. 1984). CP (b) and (c) have Cu atoms in the  $\text{CaCu}_5$  type structure (Kripyakevich 1977). Upon formation of the superstructure of the  $\text{CeCo}_3\text{B}_2$  type to this prototype the  $c/a$  ratio ( $=0.600$ ) decreases remarkably in comparison to the binary  $\text{RM}_5$  structures ( $c/a=0.774\text{--}0.822$ ). This is caused by the substitution of two boron atoms for two cobalt atoms in the unit cell. The CP of boron atoms changes from icosahedra to trigonal prism with three additional atoms (Kuz'ma 1983). This example shows the mechanism of the transformation of the (d)-type CP into the (e)-type CP. A classical representative of the (e)-type CP is the  $\text{AlB}_2$ -type structure (Kripyakevich 1977). A CP of the (f) type is found in the  $\text{BaAl}_4$  or the  $\text{CeGa}_2\text{Al}_2$  ST (Kripyakevich 1977) or the  $\text{Sc}_4\text{Rh}_7\text{Ge}_6$  (ST  $\text{U}_4\text{Re}_7\text{Si}_6$ , Engel et al. 1984) type structure. An intermediate position between the CP of the (d) and (e) types is occupied by Co atoms in the structure of  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$  (Braun et al. 1980). This structure is a two-dimensional hybrid of the following four types:  $\text{AlB}_2$  (trigonal prisms  $[\text{SiSc}_6]$ ), CsCl (empty tetrahedra  $(\text{Sc}_2\text{Si}_2)$ ),  $\text{AuCu}_3$  (cubooctahedra  $[\text{ScSi}_{12}]$ ) and  $\text{CeGa}_2\text{Al}_2$  (tetragonal antiprisms  $[\text{CoSc}_4\text{Si}_4]$ ) (fig. 101). A CP intermediate between (f) and (g) and between (h) and (i) [or (i) and (k)] contains the structure of

Fig. 101. Connections of fragments of  $\text{AlB}_2$ ,  $\text{CsCl}$ ,  $\text{AuCu}_3$  and  $\text{CeGa}_2\text{Al}_4$  types in the structure of  $\text{Sc}_5\text{Co}_4\text{Si}_{10}$ . The structure is presented in the projection along 001.

$\text{V}_3\text{As}_2$ -type (Berger 1977). Transformation of CP of atoms can also occur in the opposite direction, from CP 6 to CP 12. It is caused by a change of the dimensions of different atoms and their content in the structures. Other types of coordination surroundings of the smallest atoms in the structures of intermetallics are observed rarely.

Figure 102 represents generalised relations between the majority of the structure types of scandium intermetallics. Some of these relations have been established by Gladyshevsky and Bodak (1982). Relations between other structure types, published after 1980, have been established by Kotur (1995). Analysis of the structure types of intermetallic compounds leads to an enrichment and a broadening of our knowledge about relationships between structure types. These investigations are basic for the illumination of the nature of intermetallics and the functional relations between the compositions and structures of compounds and the factors which govern these changes.

## 6. Physical properties of scandium based intermetallics

Among scandium compounds and in compounds where scandium replaces other rare-earth elements, magnetic and nonmagnetic intermetallics exist, however, there are also scandium compounds showing superconductivity, although the scandium metal is neither magnetic nor shows superconductivity at atmospheric pressure. An extensive part of this section deals with interesting magnetic phenomena observed in the  $\text{ScM}_2$  ( $\text{M}=\text{Mn}, \text{Fe}, \text{Co}, \text{Ni}$ ) Laves phases. In the Mn- and Co-containing Laves phases the influence of spin fluctuations on the various physical properties is demonstrated.

Since scandium is one of the nonmagnetic elements among the rare-earth series one might expect that the physical properties of compounds with scandium and the other nonmagnetic rare-earth elements (Y, La or Lu) are the same or at least very similar. This supposition is true in principle, however because of the much smaller atomic size of scandium compared with yttrium and also lutetium a deviating physical behaviour of the corresponding scandium compounds is frequently observable.

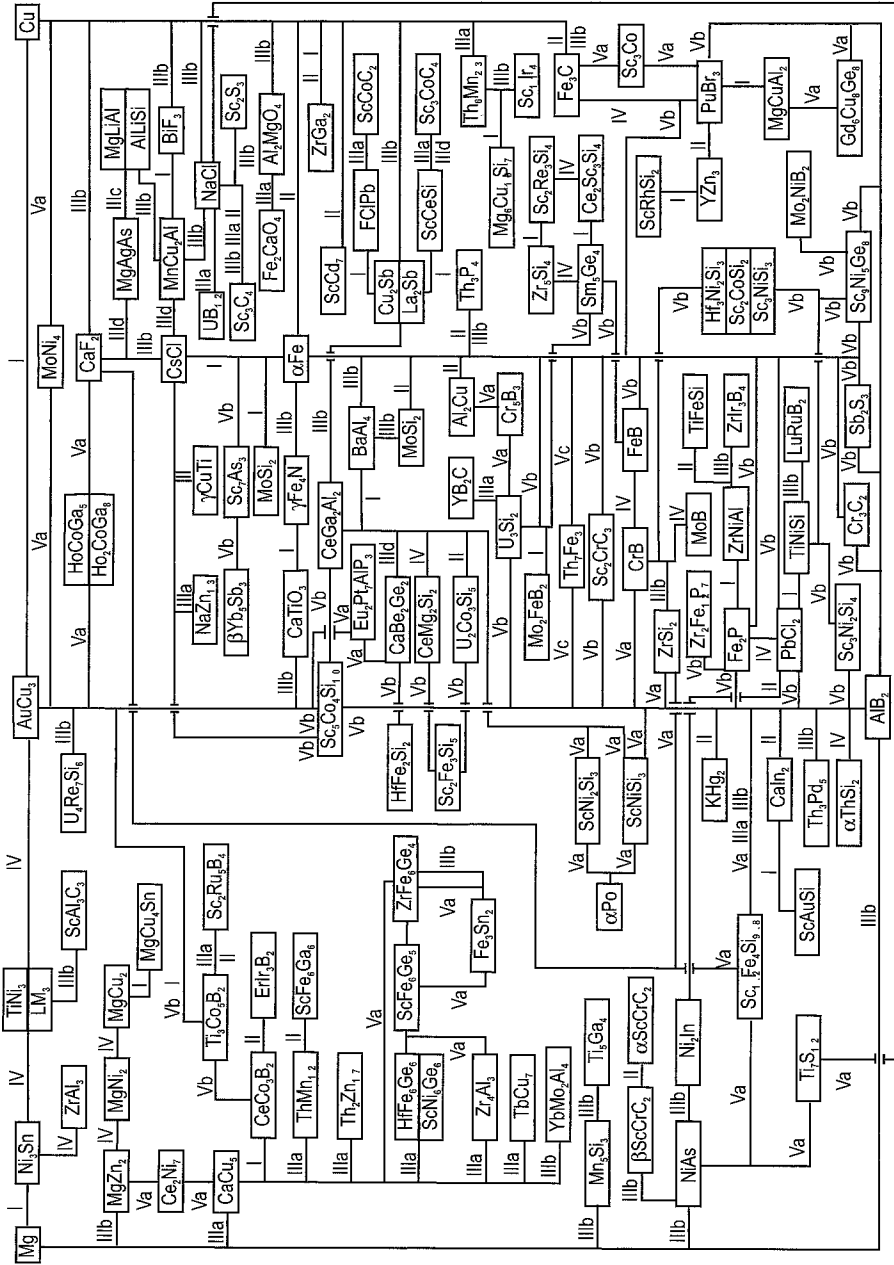

Fig. 102. Relations between structure types of Sc intermetallic compounds as derived from two close-packed structures Mg and Cu. Roman numerals I-V indicate the ways of transformation used in table 33.

## 6.1. *Compounds with non-magnetic and non-superconducting ground state*

### 6.1.1. *RAuGe (R = Sc, Y and Lu)*

The ternary RAuGe series of compounds exhibits interesting physical properties, as shown by Rossi et al. (1992) and Pöttgen et al. (1996). Details of the crystal structure, the magnetic susceptibility, the electrical resistivity, the specific heat and the electronic band structure of the four isostructural nonmagnetic RAuGe compounds (R = Sc, Y, La, Lu) have been studied recently by Schnelle et al. (1997). These four compounds are weak diamagnets. The Sc-based compound has been included in this investigation because of the small atomic size of scandium. As will be shown, the variation of the rare-earth ionic radius among this series improves our general understanding of the physical properties in this family of rare-earth intermetallics.

The structures of these compounds are derived from the  $\text{CaIn}_2$ -type structure by an ordered arrangement of the gold and germanium atoms on the indium position. The gold and germanium atoms form two-dimensional Au–Ge polyanions. However a three-dimensional network of elongated tetrahedra is present in ScAuGe (Pöttgen et al. 1996).

The degree of puckering of the Au–Ge hexagons is strongly dependent on the size of the rare-earth atoms. While the layers are almost flat in the La compound, strong puckering is observed in the other germanides. In LaAuGe and YAuGe the interlayer Au–Ge distance is 3.858 Å and 3.106 Å, respectively; the Au–Ge polyanions are two-dimensional and separated from each other. In LuAuGe the interlayer Au–Ge distance amounts to 2.927 Å, indicating a weak coupling between the layers. The transition from Au–Ge layers to a three-dimensional network of elongated tetrahedra occurs for ScAuGe. The structure of LaAuGe and YAuGe may therefore be described as being of the NdPtSb type, whereas the structures of ScAuGe and LuAuGe (with the smaller rare-earth ionic sizes) are closer to that of LiGaGe (Pöttgen et al. 1996).

The use of rare-earth atoms with different radii among this series reveals a remarkable variation of the  $c/a$  ratio (ScAuGe:  $c/a = 1.589$ , LaAuGe:  $c/a = 1.830$ ) which leads to a flattening of the three-dimensional Au–Ge network of elongated tetrahedra (in ScAuGe) towards LaAuGe accompanied by an increasing of the coupling between the Au–Ge layers in the  $c$ -direction. The electronic band structure and the density of states deduced from this calculation is in general similar for the compounds with Sc, Y and Lu. Only LaAuGe shows some small but important differences. In fig. 103 the calculated densities of states of the four compounds are shown and can be compared. The Ge  $s$  bands are around 11 eV below  $\epsilon_F$ , except for LaAuGe where the Ge  $s$  bands are about 1 eV higher in energy. The Au  $d$  bands are situated at around  $-6$  eV and again these bands are 1 eV higher in LaAuGe. For LuAuGe the Lu  $f$  bands coincide with the  $d$  bands. The lowest unoccupied bands are the Sc, Y, La or Lu  $d$  bands. The densities of states at the Fermi level  $N_F$  are: ScAuGe, 1.4, YAuGe, 0.6, LaAuGe, 2.1, LuAuGe, 0.4 in units of  $\text{eV}^{-1}$  for two spins and one RAuGe formula unit. The higher density of states of the LaAuGe compound explains its exceptional behaviour among the four compounds in this series. This will be seen from the discussion of other physical properties. The magnetic susceptibility ( $\chi$ ) of the RAuGe compounds in a field of 4 T is shown in fig. 104. An attempt to fit their

Fig. 104. Magnetic susceptibility of the RAuGe compounds at a field of 4 T (Schnelle et al. 1997).

Fig. 103. The density of states of ScAuGe, YAuGe, LaAuGe and LuAuGe. The dashed line (at  $E=0$ ) is the Fermi level (Schnelle et al. 1997).

$\chi(T)$  behaviour has been undertaken using the following formula:  $\chi(T) = C/T + \chi_0 + aT$ . The upturn in the region below 50 K described by the Curie-term ( $C/T$ ) is thought to be due to magnetic impurities. The temperature-independent part  $\chi_0$  is the sum of the diamagnetic susceptibility of the closed shell and conduction-electron contributions. The linear decrease in case of ScAuGe, LaAuGe and LuAuGe towards room temperature is taken into account by the  $aT$  term and has been attributed to a temperature dependence of the conduction-electron susceptibility.

The specific heat data have been analysed in a  $c_p/T$  vs.  $T^2$  representation. From the respective intercepts and the slopes of the straight lines fitted to the data the electronic specific heat coefficient  $\gamma$  and the Debye temperature  $\Theta_D$  at lowest temperature are obtained. While the ScAuGe, YAuGe, and LuAuGe compound exhibit  $\gamma$  values below  $1 \text{ mJ mol}^{-1} \text{ K}^{-2}$ , LaAuGe has a markedly larger electronic specific term of  $2.5 \text{ mJ mol}^{-1} \text{ K}^{-2}$ . The so-called Wilson ratio  $\chi_P/\gamma$  (where  $\chi_P$  denotes the Pauli susceptibility of the conduction electrons) is similar for YAuGe, LaAuGe, and LuAuGe, however the values are enhanced over the value of unity expected for a Fermi–Sommerfeld

free electron gas. Values between 3.6 and 3.8 are found for the Y, La and Lu compound, while for ScAuGe 6.4 has been obtained (the possible reasons for this high value have been discussed by Schnelle et al. 1997).

LaAuGe exhibits the highest values of  $\gamma$  and  $\chi_p$  among the four compounds. This correlates well with the larger density of states obtained in the band-structure calculations. Similar observations have been made in other series, namely LaAl<sub>2</sub>, YAl<sub>2</sub> and LuAl<sub>2</sub> (Hungsberg and Gschneidner 1972, Bauer et al. 1985), and LaAg, YAg and LuAg (Bauer et al. 1986) for the corresponding La compounds. In this latter cases the La compounds show superconductivity below 4.2 K. Thus it might be that also in LaAuGe a superconducting transition exists at temperatures below 4.2 K. The much stronger curvature of the  $\rho(T)$  curves of LaAuGe (shown in figure 7 of Schnelle et al. 1997) is obviously a further indication for the possibility of superconductivity in this compound.

### 6.1.2. Crystal field parameters of lanthanides diluted in ScAl<sub>2</sub>, YAl<sub>2</sub> and LuAl<sub>2</sub>

An example where a Sc compound is included in a systematic investigation (because of its small lattice parameter) is described as follows. A systematic inelastic neutron scattering experiment has been performed by Frick and Loewenhaupt (1985) on diluted lanthanide elements in the nonmagnetic matrix of ScAl<sub>2</sub>, YAl<sub>2</sub> and LaAl<sub>2</sub>. The aim was to obtain information about the origin of the crystal field (CF) in metals in general and especially to determine a set of CF parameters for the lanthanides when diluted in different nonmagnetic matrices of cubic Laves phases.

The concentration of the lanthanide elements in the hosts ScAl<sub>2</sub>, YAl<sub>2</sub> and LaAl<sub>2</sub> was chosen to be between 0.3 and 3 at%. The time-of-flight experiment was performed at an elevated temperature where the neutrons can gain energy from the system. The intensity caused by magnetic scattering was limited to the energy range below 10 meV, and it is well separated from the phonon intensity which is typically in the range of about 10 to 30 meV. The scattering data was then fitted to a theoretical model given in Becker et al. (1977) yielding the temperature-independent CF parameters  $x$  and  $W$  in the Lea–Leask–Wolf notation (Lea et al. 1962). From  $x$  and  $W$  the parameters  $A_4(r^4)$  and  $A_6(r^6)$  and finally  $A_4$  and  $A_6$  were calculated using  $(r^n)$  from Freeman and Desclaux (1979). The resultant crystal field parameters  $A_4$  and  $A_6$  in the hosts (ScAl<sub>2</sub>, YAl<sub>2</sub> and LaAl<sub>2</sub>) are plotted as a function of the atomic number of the lanthanide element in fig. 105. (There are no data for the CF levels of the elements Pm, Sm, Eu and Gd because Pm does not exist naturally, the CF of Sm, Eu show the influence of higher multiplets, and the CF influence is zero in Gd). As can be seen the  $A_4$  values are all positive whereas all the  $A_6$  values are negative. The values of  $A_4$  and  $A_6$  increase from ScAl<sub>2</sub> to YAl<sub>2</sub> to LaAl<sub>2</sub>. The variation of  $A_4$  and  $A_6$  with the atomic number shows a similar behaviour for the three matrices. A calculation of the electronic potential of the point charges surrounding the 4f ions leads to negative  $A_4$  and  $A_6$  values, assuming positive charges of the same order for Sc, Y, La and Al. Taking into account the difference in the lattice constant of ScAl<sub>2</sub>, YAl<sub>2</sub> and LaAl<sub>2</sub> and the difference in the electronegativity of Sc, Y and La, the relative distance between the  $A_4$  and  $A_6$  levels from in experiment and those calculated

Fig. 105. The experimentally determined crystal field parameters  $A_4$  and  $A_6$  in the hosts  $\text{ScAl}_2$ ,  $\text{YAl}_2$  and  $\text{LaAl}_2$  as a function of the rare-earth atom [the elements Pm, Sm, Eu and Gd do not exist naturally (Pm), show the influence of higher CF level (Sm, Eu), or the CF influence is zero (Gd)] (Frick and Loewenhaupt 1985).

are in agreement. However the more surprising observation was the positive sign of the  $A_4$  CF parameters which should be negative as are the  $A_6$  values according to the simple point-charge calculation. In the paper of Frick and Loewenhaupt (1985) it is argued that not well-screened effective point charges on the neighbouring atoms of the 4f ions and the nonspherical conduction electrons are responsible for the shape of the CF potential in  $\text{RAl}_2$  and especially for the deviation of the experiment from the calculation based on a simple point-charge model.

### 6.1.3. Spin fluctuations in $\text{RCO}_2$ compounds ( $R = \text{Sc}, \text{Y}, \text{Lu}$ )

$\text{ScCo}_2$  crystallises in the cubic Laves phase type structure. It belongs to the family of the rare-earth-transition metal compounds with 1:2 stoichiometry where the magnetic state of the Co sublattice is strongly influenced by the magnetic partner elements. In compounds with magnetic rare-earth atoms as partner elements, induced moments appear on the Co sites in the magnetically ordered state. These induced 3d moments exist only in the presence of a magnetic surroundings and range from  $1.05\mu_B$  in  $\text{GdCo}_2$  down to  $0\mu_B$  in  $\text{ScCo}_2$ ,  $\text{YCo}_2$  and  $\text{LuCo}_2$ . Due to the variability of the Co moments in combination with the stable permanent moments on the lanthanide atoms in the magnetically ordered  $\text{RCO}_2$  compounds Bloch and Lemaire (1970) used the concept of the exchange-enhanced paramagnetism for the Co sublattice and developed a phenomenological model to describe the exchange-induced moment on Co. From this model it was deduced that the R-Co interaction is about twice as strong as the Co-Co interaction, which is in agreement with investigations of the magnetoelastic properties first performed by Lee and Pourarian (1976). The magnetic fields available nowadays in some laboratories are high enough to exit the critical field for induced Co moments in  $\text{YCo}_2$  which is about 70 T (Goto et al. 1990). These three Co-based Laves phases to which  $\text{ScCo}_2$  belongs are enhanced paramagnets. The temperature variation of the susceptibility shows maxima at elevated temperatures ( $\text{YCo}_2$ : 260 K,  $\text{LuCo}_2$ : 370 K,  $\text{ScCo}_2$ : 550 K, see fig. 106) whereas in the low-temperature region an increase of  $\chi(T)$  proportional to  $T^2$  has been found (Burzo et al. 1993). The  $\chi$ -values at 0 K as given by Ikeda et al. (1991) are:  $\chi(\text{YCo}_2) = 6.0$ ,  $\chi(\text{LuCo}_2) = 3.96$ ,  $\chi(\text{ScCo}_2) = 3.67$  in units of  $10^{-4} \text{ emu}/(\text{g-atom})$ . The values for  $\text{YCo}_2$  and  $\text{LuCo}_2$  are not in complete agreement with the data shown in fig. 106 at the lowest

Fig. 106. The high-field dc magnetic susceptibility of the three spin fluctuation systems  $\text{ScCo}_2$ ,  $\text{YCo}_2$  and  $\text{LuCo}_2$  (Burzo et al. 1993).

temperatures. This is however not surprising, since the  $\chi$ -values are strongly influenced by the quality of the sample material (Steiner and Ortbauer 1974 found that grinding of the sample material can cause a rise in susceptibility by a factor of three).

There is also an enhancement of the electronic specific heat coefficients  $\gamma$  ( $\gamma(\text{YCo}_2) = 33.1$ ,  $\gamma(\text{LuCo}_2) = 26.6$ , and  $\gamma(\text{ScCo}_2) = 18.4$  in units of  $\text{mJ}(\text{mol-Co})^{-1} \text{K}^{-2}$ ) (Ikeda et al. 1991), which in the case of  $\text{ScCo}_2$  is larger by a factor of three than that of  $\text{ScNi}_2$ .

The concept of spin fluctuations (details are given in the book by Moriya 1985) has been successfully used to describe the enhanced  $\gamma$ -value and the temperature variation of the susceptibility. The influence of spin fluctuations on the transport phenomena in these  $\text{RCO}_2$  compounds ( $\text{R} = \text{Sc}, \text{Y}, \text{Lu}$ ) has been investigated recently by Gratz (1997).

Spin fluctuations contribute to the transport phenomena since they scatter conduction electrons through the exchange interaction. This problem has been treated using a two-band model where the electrons in the conduction band carry charge or heat while those in the narrow d band contribute to the spin fluctuations which scatter the conduction electrons through the s-d exchange interaction. The first publications dealing with this problem date back to the late 1960s (Mills and Lederer 1966, Schindler and Rice 1967, Mathon 1968). These calculations were later continued by Coqblin et al. (1978).

The results can be summarised as follows:

*Electrical resistivity:*  $\rho \propto T^2$ , with the tendency to saturate at elevated temperatures;

*Thermal resistivity:*  $W \propto T$  at low temperatures, followed by a maximum.

*Magnetoresistance:*  $(\Delta\rho/\rho)$  is negative and proportional to the square of the applied field.

The temperature dependence of the electrical resistivity  $\rho$  of  $\text{ScCo}_2$ ,  $\text{YCo}_2$  and  $\text{LuCo}_2$  is shown in fig. 107. To illustrate the influence of the spin fluctuation scattering in these Co-based compounds, the  $\rho(T)$  dependence of the two isostructural non-spin-fluctuation compounds  $\text{YAl}_2$  and  $\text{LuNi}_2$  is given in this figure too. Both phonon scattering and spin-fluctuation scattering cause a change of  $\rho$  with temperature. For the spin-fluctuation contribution to  $\rho(T)$  the curvature at elevated temperatures and the  $T^2$  increase at low temperatures is confirmed by the experiment. A quantitative analysis of  $\rho(T) - \rho_0$  versus  $T^2$  is depicted in the inset of fig. 107. The low-temperature resistivity is dominated by the quadratic increase due to the spin-fluctuation scattering giving rise to the enhanced

Fig. 107. The electrical resistivity of ScCo<sub>2</sub>, YCo<sub>2</sub> and LuCo<sub>2</sub> from 4 K to 1000 K, where  $\rho_0(\text{RCO}_2) = 18, 24$  and  $17 \mu\Omega\text{cm}$ , respectively. The increase of  $\rho(T)$  in the non-spin-fluctuation systems YAl<sub>2</sub> and LuNi<sub>2</sub> ( $\rho_0 = 5.6$  and  $4.2 \mu\Omega\text{cm}$ , respectively) is shown for comparison. Inset: low-temperature  $T^2$  dependence of the spin fluctuation systems (Gratz 1997).

Fig. 108. The thermal conductivity of ScCo<sub>2</sub>, YCo<sub>2</sub>, LuCo<sub>2</sub> and YAl<sub>2</sub> from 4 K to 300 K. Inset: the fit of  $\lambda(T) = (aT^{-1} + bT^2 + cT)^{-1} + dT^2$  to the experimental data is given by the solid lines (Gratz 1997).

factor  $A$ . According to the theory of spin fluctuations (Coqblin et al. 1978) the factor  $A$  is related to the corresponding spin-fluctuation temperatures by the relation  $A \propto T_{\text{sf}}^{-2}$ . This factor has the following values:  $A(\text{YCo}_2) = 16$ ,  $A(\text{LuCo}_2) = 12$  and  $A(\text{ScCo}_2) = 4.3$  in units of  $\text{n}\Omega \text{cm K}^{-2}$ . The thermal conductivity  $\lambda$  of these spin-fluctuation systems is shown in fig. 108 (again the  $\lambda(T)$  curve for YAl<sub>2</sub> is included). In the spin-fluctuation compounds one observes a pronounced curvature in  $\lambda(T)$  in the region  $20 \text{ K} \leq T \leq 60 \text{ K}$  which is not observable in YAl<sub>2</sub>. For temperatures higher than about 50 K  $\lambda(T)$  is nearly constant and decreases from ScCo<sub>2</sub> towards YCo<sub>2</sub>. Since the analysis of thermal conductivity data is not frequently shown in the literature it should be outlined here in more detail. Using the theoretically obtained  $\lambda(T)$  dependencies for the different scattering processes (see also Ziman 1960), one can account for the variation of  $\lambda(T)$  at low temperatures:

$$\lambda(T) = \lambda_c + \lambda_1 = \frac{1}{W_{e,0} + W_{e,\text{ph}} + W_{e,\text{sf}}} + \lambda_1,$$

where  $\lambda_c$  and  $\lambda_1$  denote the electronic and the lattice thermal conductivity, respectively, and  $W_{e,0}$ ,  $W_{e,\text{ph}}$  and  $W_{e,\text{sf}}$  are the thermal resistivities due to impurity-, phonon- and spin-

Fig. 109. The thermopower of  $\text{ScCo}_2$ ,  $\text{YCo}_2$ ,  $\text{LuCo}_2$  and  $\text{YAl}_2$  from 4 K to 1000 K. Inset: correlation between the position of the high-temperature minima  $T_{\min}$  and the  $\gamma$  value of the specific heat in  $\text{ScCo}_2$ ,  $\text{YCo}_2$  and  $\text{LuCo}_2$  (Gratz 1997).

fluctuation-scattering processes, respectively). With  $W_{e,0} \propto 1/T$ ,  $W_{e,\text{ph}} \propto T^2$ ,  $W_{e,\text{sf}} \propto T$  and  $\lambda_1 \propto T^2$  we finally obtain

$$\lambda(T) = \frac{1}{a(1/T) + bT^2 + cT} + dT^2.$$

Using the Wiedemann–Franz law, the coefficient  $a$  can be determined from the residual electrical resistivity  $\rho_0$ . Least-squares fits to the experimental data up to 75 K are given by the solid lines in the inset of fig. 108. Interestingly the fit procedure shows that the  $W_{e,\text{ph}}$  term is much smaller compared to  $W_{e,\text{sf}}$  in these  $\text{RCO}_2$  series. The linear  $W_{e,\text{sf}}$  term is dominating and responsible for the pronounced curvature in  $\lambda$  vs.  $T$  between 20 K and 60 K. The  $c$ -values ( $W_{e,\text{sf}} = cT$ ) are related to the spin-fluctuation temperatures  $c \propto T_{\text{sf}}^{-1}$  (Coqblin et al. 1978). The  $c$ -values are:  $c(\text{YCo}_2) = 23 \times 10^{-5}$ ,  $c(\text{LuCo}_2) = 21 \times 10^{-5}$ , and  $c(\text{ScCo}_2) = 11 \times 10^{-5}$  in units of  $\text{cm}/\text{mW}$ . Note that, from the tendency of the  $c$ -values as well as from the  $A$  coefficients in  $\rho_{\text{sf}}(T) = AT^2$ , it follows that  $T_{\text{sf}}(\text{YCo}_2) < T_{\text{sf}}(\text{LuCo}_2) < T_{\text{sf}}(\text{ScCo}_2)$ .

In fig. 109 the temperature dependence of the thermopower  $S$  of the  $\text{RCO}_2$  compounds is depicted and compared with  $\text{YAl}_2$ . Note that in the Co compounds the minima in  $S$  vs.  $T$  at low temperature are much more pronounced than in the non-spin-fluctuation system  $\text{YAl}_2$ . The tiny minimum at low temperature, existing also in  $\text{YAl}_2$ , has been referred to as ‘phonon drag’ effect (Gratz and Nowotny 1985). In general such a ‘drag effect’ is thought to be caused by the situation that, in addition to the conduction electron system, other subsystems (phonons or magnons) are thermally in non-equilibrium and may cause an additional contribution to the total thermopower. This is usually taken into account by putting  $S_{\text{tot}} = S_{\text{diff}} + S_{\text{drag}}$ , where  $S_{\text{diff}}$  and  $S_{\text{drag}}$  are the diffusion and drag terms (Ziman 1960). Although no theoretical confirmation for such a ‘paramagnon drag effect’ yet exists, experimentally minima (or sometimes maxima, depending on the slope of the density-of-states function at  $\varepsilon_{\text{F}}$ ) have been observed in many paramagnetic spin fluctuation systems near their spin fluctuation temperatures, e.g. in  $\text{UAl}_2$  (Coqblin et al. 1978). The broad minima at elevated temperatures are intimately correlated to changes of  $dN(\varepsilon)/d\varepsilon$  at  $\varepsilon_{\text{F}}$  with temperature (Gratz et al. 1995). Density-of-states properties at the Fermi level

Fig. 110. The locations of the three  $R\text{Co}_2$  ( $R = \text{Sc}, \text{Y}, \text{Lu}$ ) spin fluctuation systems in the Kadowaki-Woods plot.

$[N(\varepsilon_F)$  and  $dN(\varepsilon)/d\varepsilon$  at  $\varepsilon_F$ ] are much more important for the diffusion thermopower at high temperature than for any of the other transport phenomena (Ziman 1960, Gratz et al. 1995). A correlation between the position of the high-temperature minima  $T_{\min}$  in  $S(T)$  and the  $\gamma$ -value of the specific heat has been found by Gratz et al. (1995) and is shown in the inset of fig. 109. As has been shown by Kadowaki and Woods (1986) there exists an important relation between  $A$  (the prefactor in  $\rho = AT^2$ ) and the coefficient of the electronic specific heat  $\gamma$  for all strongly correlated electron systems. As such a Kadowaki-Woods plot (fig. 110) shows, the positions of the three  $R\text{Co}_2$  spin-fluctuation systems fall in the range where many of the other known spin-fluctuation systems, such as  $\text{Sc}_3\text{In}$ ,  $\text{YMn}_2$  (under pressure in the paramagnetic state)  $\text{UPt}_2$  or  $\text{UAl}_2$ , lie.

It follows from these data that spin fluctuations significantly influence transport phenomena. The question of whether these kinds of excitations (such as spin fluctuations) can be observed in an experiment depends on their characteristic time scale and the time window of the experiment used. An estimation of the characteristic time window of the transport phenomena gives about  $10^{-14}$  s, which is of the same order of magnitude as the time scale of spin fluctuations in the d-electron subsystem.

## 6.2. Compounds with magnetic ground state

### 6.2.1. $\text{Sc}_3\text{In}$

$\text{Sc}_3\text{In}$  crystallises in the  $\text{Ni}_3\text{Sn}$ -type structure (SG:  $P6_3/mmc$ ) and has been classified as a weak ferromagnetic material. The onset of long-range ferromagnetic order as reported in the literature is between 5.5 K and 6 K depending on the stoichiometry of the sample (see Ikeda and Gschneidner 1981). The itinerant character of a ferromagnetic compound can best be seen from a so-called Rhodes-Wohlfarth plot (Rhodes and Wohlfarth 1963, Wohlfarth 1978) where  $p_s$  is the saturation moment per magnetic atom and  $p_c$  the effective moment per magnetic atom deduced from the Curie constant. Figure 111 shows the location of  $\text{Sc}_3\text{In}$  within a Rhodes-Wohlfarth plot. The  $p_c/p_s$  ratio for  $\text{Sc}_3\text{In}$  is 6.1 (Matthias et al. 1961), which is remarkably beyond the local moment limit of  $p_c/p_s = 1$  for a strongly localised magnetically ordered material such as, e.g., Gd. In the local

Fig. 111.  $p_C/p_S$  vs.  $T_C$ , a Rhodes–Wohlfarth plot;  $p_S$  is the saturation moment per magnetic atom and  $p_C$  is the corresponding effective moment deduced from the Curie constant (Wohlfarth 1978).

Fig. 112. The temperature dependence of the electrical resistivity of  $Sc_3In$  in different external magnetic fields. Inset: the  $T^2$  dependence of the resistivity under the influence of the magnetic fields (Ikeda et al. 1984).

moment limit  $p_C/p_S = 1$ , and in the opposite weakly ferromagnetic limit theory predicts the divergence of this ratio as  $p_S \rightarrow 0$  or  $T_C \rightarrow 0$ , since the Curie constant in this case is independent of  $p_S$  or  $T_C$ .

The effect of spin fluctuations in ferromagnetic and nearly ferromagnetic metals has been the subject of considerable interest for a long time. First Moriya and Kawabata (1973a,b) have developed a theory which considers the effect of spin fluctuations in a self-consistent way, thus taking account of the interaction among the spin-fluctuation modes. For the description of the magnetic properties of  $Sc_3In$  the concept of spin fluctuations is used. Ikeda and Gschneidner (1981) performed measurements of the specific heat and resistivity (Ikeda et al. 1984) in external fields with the aim to show that in materials with large spin-fluctuation enhancement, it is possible that a field of 10 T is sufficient to produce a measurable change in the magnetic specific heat and the low-temperature resistivity behaviour. Some of these results are given in the following figures. Figure 112 shows the temperature dependence of the electrical resistivity in different magnetic fields. The zero-field measurement clearly shows a kink in  $\rho(T)$  indicating the Curie temperature at about 6 K. The inset shows a  $T^2$  plot of the electrical resistivity at 0 T, 1 T, 2.5 T, 5 T and 7.5 T. As can be seen there is a  $T^2$  dependence up to about 4 K. The prefactor  $A$  in the  $\rho = AT^2$  relation strongly decreases with increasing field and becomes constant roughly above 5 T. The strong decrease of  $A$  with the magnetic field has been referred to as quenching of spin fluctuations. It should be noted however, that one always observes a negative magnetoresistance  $\Delta\rho/\rho_0 \equiv [\rho(B) - \rho(B = 0)]/\rho(B = 0)$  in ferromagnets around  $T_C$  with a minimum in  $\Delta\rho/\rho_0$  vs.  $T$  at  $T_C$  (Fournier and Gratz 1993). **The minimum at  $T_C$  in  $\Delta\rho/\rho_0$  vs.  $T$  is more pronounced the lower the ferromagnetic transition takes place.** If this is taken into account the question arises whether this experiment can be considered as a test for the suppression of spin fluctuations in  $Sc_3In$ .

Fig. 113. The temperature dependence of the magnetic contribution to the specific heat  $c_m$ , in different magnetic fields (Ikeda and Gschneidner 1981).

Specific-heat experiments in magnetic fields performed by Ikeda and Gschneidner (1981) are presented in fig. 113, showing the magnetic contribution to the specific heat determined from the analysis of the experimental data by  $c_m = c - \gamma T - \beta T^3$ . As can be seen from this figure,  $c_m$  becomes smaller with increasing magnetic field, and in fields of about 10 T the height of its peak around  $T_C$  is only about  $\frac{1}{4}$  of the zero-field value. Moreover, another peak around 8–9 K is found to be more pronounced at 5.4 T than in the highest field of 10 T. This new peak is thought to be due to the induced magnetisation of  $\text{Sc}_3\text{In}$  by the magnetic field.

### 6.2.2. $\text{ScFe}_2$ and related compounds

Among the  $\text{RFe}_2$  series only  $\text{ScFe}_2$  crystallises in a hexagonal Laves phase ( $\text{MgZn}_2$  type structure) whereas all the remaining compounds have the cubic Laves phase ( $\text{MgCu}_2$  type structure). All these  $\text{RFe}_2$  Laves phases ( $\text{ScFe}_2$  included) form ferromagnets with the nonmagnetic lanthanides and co-linear ferromagnets with the light lanthanides, or a ferrimagnetic structure with the heavy lanthanides with comparatively high Curie temperatures ( $>500$  K). The high  $T_C$  values are primarily caused by the strong Fe–Fe exchange interaction. The ferromagnetic transition temperature of a  $\text{ScFe}_2$  sample with the exact 1:2 stoichiometry is close to 540 K (see below). The magnetic moments per Fe atom vary roughly from  $1.4\mu_B$  in case of Sc, Y and Lu to  $1.8\mu_B$  for the compounds with the magnetic lanthanides as partner elements, thus proving that the Fe sublattice does not reach the saturated state in  $\text{ScFe}_2$ ,  $\text{YFe}_2$  and  $\text{LuFe}_2$  (Rhyne 1987, Franse and Radwanski 1993). Band-structure calculations in the paramagnetic state of  $\text{ScFe}_2$  by Ishida and Asano (1985) revealed that there is a peak in the density of states (DOS) due to the 3d bands of iron at the Fermi level on both Fe sites (2a and 6h). However, there is a small difference found in the DOS between Fe(2a) and Fe(6h) revealing different magnetic moments of  $1.4\mu_B/\text{Fe}(2a)$  and  $1.46\mu_B/\text{Fe}(6h)$ . This bandstructure calculation also reveals an induced magnetic moment on the Sc sites of  $0.27\mu_B/\text{Sc}$  with the direction opposite to the moments on the Fe sites. However, these induced Sc–moments have not yet been observed experimentally. The calculated value of the

magnetic moments per formula unit is within the range of experimental values obtained by magnetic measurements;  $2.9\mu_B/\text{ScFe}_2$  (Sankar and Wallace 1976),  $2.23\mu_B/\text{ScFe}_{1.96}$  and  $2.75\mu_B/\text{ScFe}_{2.05}$  (Grössinger et al. 1980). All these experimental values were obtained neglecting the existence of an induced Sc-moment as predicted by the theory. The slightly different values for the magnetic moments on the Fe(2a) and Fe(6h) sites are confirmed by differences in the hyperfine field observed in the Mössbauer effect which are 170 kOe for Fe(2a) sites and 176 kOe for Fe(6h) (Grössinger et al. (1980)). These authors investigated the influence of the stoichiometry on the bulk magnetisation and the hyperfine interaction by studying a second sample with a different Fe content:  $\text{ScFe}_{2.05}$ . They showed that the magnetocrystalline anisotropy differs considerably in magnitude depending on the composition. The average hyperfine field at 4.2 K increases from 176 kOe for the sample  $\text{ScFe}_{1.96}$  up to 201 kOe in the sample  $\text{ScFe}_{2.05}$ . The conclusion drawn by Grössinger et al. (1980) is that the magnetic behavior of  $\text{ScFe}_2$  is obviously very sensitive to the average  $d_{\text{Fe-Fe}}$  value. These arguments are further supported by the study of a hydrogenised  $\text{ScFe}_2$  sample ( $\text{ScFe}_2\text{H}_2$ ) (Smit and Buschow 1980) where the lattice constants are  $a=5.279 \text{ \AA}$ ,  $c=8.507 \text{ \AA}$  (to be compared with  $a=4.977 \text{ \AA}$ ,  $c=8.146 \text{ \AA}$  for  $\text{ScFe}_2$ ). By means of magnetic measurements an increase of the moment per Fe from  $1.4\mu_B$  in  $\text{ScFe}_2$  to  $2.2\mu_B$  in  $\text{ScFe}_2\text{H}_2$  has been found. Using  $^{57}\text{Fe}$  Mössbauer spectroscopy an increase of the hyperfine splitting by about 60% was observed, whereas, on the other hand, only a rather small change in the isomer shift was observed in  $\text{ScFe}_2\text{H}_2$ . Arguments are given in Smit and Buschow (1980) that it is difficult to explain the moment change in terms of a single 3d band picture and charge-transfer effect.

The dependence of the Curie temperature on the composition in  $\text{ScFe}_2$  has been studied by the authors (Kotur et al. 1998). This investigation showed that a sample with the composition 1:1.92 exhibits an increase of the Curie temperature by about 100 K compared to the sample with the 1:2 stoichiometry with  $T_C=540 \text{ K}$ . This sensitivity of the magnetic properties to the composition has been suggested to be due to the chemical pressure the Fe atoms experience in this Sc-based hexagonal Laves phase. As noted above the  $\text{ScFe}_2$  compound does not crystallize in the cubic  $\text{MgCu}_2$ -type structure, which is obviously due to the much smaller atomic radius of Sc. Furthermore, a change in the structural surroundings also influences the magnetic properties. Xia et al. (1996) have shown that a partial chemical disorder produced by ball milling leads to an increase of the Fe moment. Finally, amorphisation due to a long-lasting ball milling reduces the Curie temperature from 540 K down to 250 K (Xia et al. 1996).

For purpose of comparison the magnetic susceptibilities (or the magnetisations) of  $\text{ScNi}_2$ ,  $\text{ScCo}_2$  and  $\text{ScFe}_2$ , respectively, are shown in fig. 114. This picture clearly shows that among the  $\text{ScM}_2$  ( $M=\text{Ni, Co, Fe}$ ) there is one weak paramagnet ( $\text{ScNi}_2$ ), one enhanced paramagnet ( $\text{ScCo}_2$ , see also sect. 6.1.3) and the ferromagnetic compound  $\text{ScFe}_2$ , with a long-range ferromagnetic order, caused by the 3d exchange interaction.

Another comparison has been made in fig. 115, where the temperature dependence of the electrical resistivity of these three compounds is depicted. It is interesting to note that although  $\text{ScCo}_2$  does not show a long-range magnetic order, there is a huge magnetic contribution to the total resistivity,  $\rho_{\text{mag}}(T) = \rho_{\text{ges}} - \rho_0 - \rho_{\text{ph}}$ , which is of the same

Fig. 114. The temperature dependence of the dc susceptibility of  $\text{ScNi}_2$  and  $\text{ScCo}_2$  (Kotur et al. 1998), and the magnetization of  $\text{ScFe}_2$  (in a field of 4.5 T) (Sankar and Wallace 1976).

Fig. 115. A comparison of the electrical resistivity of  $\text{ScFe}_2$ ,  $\text{ScNi}_2$  (Kotur et al. 1998) and  $\text{ScCo}_2$  (Gratz 1997). Inset: the low-temperature  $T^2$  dependence of the three Fe-based ferromagnetic Laves phases (Kotur et al. 1998).

order of magnitude (about  $100 \mu\Omega \text{ cm}$ ) as in the ferromagnetic  $\text{ScFe}_2$  compound, with a paramagnetic moment of the order of  $1.4 \mu_B/\text{Fe}$  (see above). (The phonon resistivity  $\rho_{\text{ph}}$  for all three compounds is roughly given by the  $\rho(T)$  data of  $\text{ScNi}_2$ , the residual resistivity  $\rho_0$  has been subtracted from the data in this presentation). This picture underlines the statement in sect. 6.1.3 that the electrical resistivity (transport phenomena in general) is very sensitive to scattering processes of the conduction electrons with spin fluctuations. In sect. 6.1.3 it has been shown that there is a  $T^2$  dependence of  $\rho_{\text{mag}}(T)$  at low temperatures due to the spin-fluctuation scattering of the conduction electrons. Note that there is also a  $\rho(T) = AT^2$  dependence in  $\text{ScFe}_2$ , caused by the spin-wave (magnon) scattering of the conduction electrons (Gratz et al. 1989). However  $A$  for  $\text{ScFe}_2$  is roughly one order of magnitude smaller than the  $A$ -values found in the  $\text{RCO}_2$  spin-fluctuation systems. The inset in fig. 115 shows the  $T^2$  dependence of the resistivity for the three ferromagnetic  $\text{RFe}_2$  ( $\text{R} = \text{Sc}, \text{Y}, \text{Lu}$ ) compounds.

6.2.2.1.  $\text{Sc}(\text{M}_{1-x}\text{Si}_x)_2$  ( $\text{M} = \text{Fe}, \text{Co}, \text{Ni}$ ). As discussed in sect. 3.6, the substitution of Fe by Si in  $\text{ScFe}_2$  reveals a change of the structure from the hexagonal  $\text{MgZn}_2$ -type structure ( $\text{ScFe}_2$ ) to the cubic  $\text{MgCu}_2$  type structure, if about 6 at% of Fe are substituted

Fig. 116. Arrott plots of the  $\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2$  compound. Inset: the low-temperature magnetisation in an  $M$  vs.  $T^{3/2}$  representation. The spin wave stiffness thus obtained is  $66 \text{ meV \AA}^3$  (Kotur et al. 1998).

by Si. The  $\text{MgZn}_2$ -type structure reappears around a substitution of 16 at% Fe by Si (Gladyshevsky et al. 1977). The influence of the Si substitution on the physical properties in the series of the  $\text{Sc}(\text{Fe}_{1-x}\text{Si}_x)_2$  has been investigated by Kotur et al. (1998). In this investigation the Co- and Ni-based  $\text{Sc}(\text{M}_{1-x}\text{Si}_x)_2$  compounds are included. Starting with  $\text{ScFe}_2$ , two other samples,  $\text{Sc}(\text{Fe}_{0.94}\text{Si}_{0.06})_2$  with the  $\text{MgCu}_2$ -type structure and  $\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2$  with the  $\text{MgZn}_2$ -type structure have been investigated in order to study the change of the magnetic properties due to the Fe substitution. For this study a number of measuring methods, namely magnetisation, specific heat, thermal expansion, resistivity and Mössbauer spectroscopy have been utilized by Kotur et al. (1998). The cubic sample  $\text{Sc}(\text{Fe}_{0.94}\text{Si}_{0.06})_2$  shows a small decrease of  $T_C$  whereas all the other physical properties are similar to those of  $\text{ScFe}_2$ . These investigations however revealed that there is a dramatic lowering of the onset of the magnetic order in the sample  $\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2$  ( $T_C = 145 \text{ K}$ ) in combination with a decrease of the averaged Fe moment ( $0.67\mu_B/\text{Fe}$ ). The  $M^2$  vs.  $B/M$  plot (Arrott plot) of the sample  $\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2$  is given in fig. 116. The curvature of the  $M^2$  vs.  $B/M$  curves in the ordered state was thought to be due to the local character of the Fe moments in these compound. The inset in fig. 116 shows the low-temperature magnetisation in a  $M$  vs.  $T^{3/2}$  representation. From this an estimation of the spin-wave stiffness constant has been obtained. The value for  $\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2$  is  $66 \text{ meV \AA}^3$ , which is distinctly reduced when compared to  $\text{ScFe}_2$  ( $465 \text{ meV \AA}^3$ ).

The resistivity behaviour for the sample with  $\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2$  is remarkable, since there is a negative slope in the temperature range from 4 K up to room temperature. The normalised resistivity curves ( $\rho(T)/\rho(295 \text{ K})$  vs.  $T$ ) for the  $\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2$  sample, together with the resistivity of the isostructural Co- and Ni-based compounds  $\text{Sc}(\text{Co}_{0.75}\text{Si}_{0.25})_2$ , and  $\text{Sc}(\text{Ni}_{0.75}\text{Si}_{0.25})_2$  are given in fig. 117. The residual resistivity for these compounds is of the order of  $300\text{--}400 \mu\Omega \text{ cm}$ . This has been interpreted as a sign for a charge transfer from the silicon p bands to the 3d band of Fe, Co or Ni and the begin of a gap-opening.

There is an increase of the electronic specific heat coefficient  $\gamma$  from  $\gamma(\text{ScFe}_2) = 10 \text{ mJ mol}^{-1} \text{ K}^{-2}$  to  $\gamma(\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2) = 38 \text{ mJ mol}^{-1} \text{ K}^{-2}$ .  $\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2$  has a small thermal expansion coefficient ( $\alpha = 12 \times 10^{-6} \text{ K}^{-1}$ ) without any anomaly at  $T_C = 145 \text{ K}$ .

Fig. 117. The normalised resistivity  $\rho(T)/\rho(295\text{ K})$  for  $\text{Sc}(\text{Fe}_{0.75}\text{Si}_{0.25})_2$ ,  $\text{Sc}(\text{Co}_{0.75}\text{Si}_{0.25})_2$ , and  $\text{Sc}(\text{Ni}_{0.75}\text{Si}_{0.25})_2$  (Kotur et al. 1998).

These investigations also revealed that an annealing procedure as well as a change of the 1:2 stoichiometry within the corresponding homogeneity range changes the physical properties considerably.

6.2.2.2.  $(\text{Sc}_{1-x}\text{Ti}_x)\text{Fe}_2$ .  $\text{ScFe}_2$  is a ferromagnet (as shown above) whereas  $\text{TiFe}_2$  shows antiferromagnetism with  $T_N \approx 270\text{ K}$  (Nakamichi 1968). Both compounds crystallise in the hexagonal  $\text{MgZn}_2$  Laves phase structure. Thus in the pseudobinary system  $(\text{Sc}_{1-x}\text{Ti}_x)\text{Fe}_2$  the magnetic properties change from ferromagnetism to antiferromagnetism as the Sc:Ti ratio changes. The system shows the  $\text{MgZn}_2$  type structure over the whole concentration range. Along this pseudobinary the Curie temperature on the Sc-rich side (up to  $x=0.2$ ) is nearly constant with a saturation magnetisation for  $\text{ScFe}_{1.95}$  of about  $81\text{ emu/g}$  (Nishihara and Yamaguchi 1986). However, with increasing Ti concentration the saturation magnetisation increases up to about  $94\text{ emu/g}$  for  $x=0.65$  and a decreasing saturation field. This tendency however changes abruptly at about  $x=0.7$ , the saturation magnetisation for this sample is about half ( $48\text{ emu/g}$ ) of that for the sample with  $x=0.65$ . A small discontinuity at  $150\text{ K}$  in the temperature dependence of the magnetisation for  $x=0.7$  has been interpreted as the onset of antiferromagnetism in the low-temperature region causing the decrease of the saturation magnetisation (Nishihara and Yamaguchi 1985, 1986). Interestingly, in the temperature dependence of the magnetisation for  $x=0.65$  to  $x=0.4$  there is a step-like increase of the ferromagnetic magnetisation at the corresponding transition temperature (for  $x=0.65$  at  $80\text{ K}$ ) due to a temperature-induced increase of the ferromagnetic Fe moments. The saturation magnetisation at  $0\text{ K}$  is  $1.3\mu_B/\text{Fe}$  and about  $0.9\mu_B/\text{Fe}$  just above the transition temperature for the sample  $x=0.65$ . This difference in the saturation moment between both ferromagnetic states become smaller as the Ti content is further decreased. No such a transition has been found for  $0 \leq x \leq 0.2$ .

Investigations of the paramagnetic susceptibility exhibit that for all the samples the Curie–Weiss law is fulfilled however the Curie constants are larger for the sample with  $x > 0.75$  than for that with  $x < 0.5$ . Interestingly the  $\chi^{-1}$  vs.  $T$  plots for  $0.5 \leq x \leq 0.75$  show kinks at temperatures about  $100\text{ K}$  higher than the corresponding Curie temperatures. The

change in the effective moment, deduced from the Curie constant, is  $2.5\mu_B/\text{Fe}$  above the kink in  $\chi^{-1}$  vs.  $T$  and about  $1.6\mu_B/\text{Fe}$  below the kink.

It seems that this finding is a confirmation that the change in the chemical pressure the Fe atoms experience within this pseudobinary caused by the small atomic diameter (of both Sc and Ti) destabilises the magnetic moments of the Fe atoms. This is, for example, quite in contrast to  $\text{YFe}_2$  with stable moments on the iron sites.

### 6.2.3. Sc substitution in $\text{YMn}_2$

Rare-earth Laves phases with 3d transition metals as a partner element are interesting mainly because of the great variety of magnetic phenomena observed in this family of intermetallics. The intercorrelation between the two types of Laves phases C15 (cubic) and C14 (hexagonal) is similar to that between the fcc and hcp, i.e., a different order of packing of atomic layers. Therefore, the coordination number is the same for both structures. One of the characteristics of this structure is that the nearest neighbour of a transition-metal atom is also a transition-metal atom. The atomic distances between the transition metals in  $\text{RMn}_2$  is similar to that in the pure 3d metals. Comparing the density of states of the elementary "heavy" 3d elements (Mn, Fe, Co, Ni) shows that the 3d density of states is similar to that of the Laves phases  $\text{RMn}_2$ ,  $\text{RFe}_2$ ,  $\text{RCO}_2$  and  $\text{RNi}_2$ . However within one such a series the position of the Fermi level can be shifted by selecting RE elements with different atomic diameter. This is why Sc with its small atomic size is frequently used as an alloying element.

In the following a well-known example,  $\text{Y}(\text{Sc})\text{Mn}_2$ , will be discussed. In a number of investigations it has been shown that the magnetic state of Mn in these Laves phases depends sensitively on the Mn–Mn distance ( $d_{\text{Mn–Mn}}$ ) (Shiga 1988). Above a critical value of  $d_{\text{Mn–Mn}} = 2.7 \text{ \AA}$  there exist spontaneous Mn moments which in general are antiferromagnetically ordered at low enough temperatures. Below this critical  $d_{\text{Mn–Mn}}$  value the spontaneous Mn moments are zero, however, induced Mn moments can appear in  $\text{RMn}_2$  compounds with magnetic rare-earth elements as partner elements (for a review see Hauser et al. 1994). The sensitivity of the magnetic ground state to  $d_{\text{Mn–Mn}}$  is why in  $\text{YMn}_2$  a relatively small pressure of about 3 kbar is enough to suppress the antiferromagnetic order (Oomi et al. 1987). However, what is interesting for the subject under consideration, is that a substitution of a small amount of Sc in  $\text{YMn}_2$  causes also a nonmagnetic ground state, due to the negative chemical pressure. In the  $\chi$  vs.  $T$  curves of the pseudobinary  $(\text{Y}_{1-x}\text{Sc}_x)\text{Mn}_2$  system the discontinuity at  $T_N$  shifts below 4.2 K for  $x > 0.02$ , indicating the collapse of the antiferromagnetic state (Nakamura et al. 1988). Another indication for the suppression of the antiferromagnetic state within this pseudobinary system is the vanishing zero-field NMR spectrum with increasing Sc concentration (Yoshimura et al. 1987). However the collapse of the antiferromagnetic order in  $(\text{Y}_{1-x}\text{Sc}_x)\text{Mn}_2$  can most clearly be seen in the temperature dependence of the lattice parameter within this pseudobinary system. These measurements are given in fig. 118 (Shiga 1988). The sharp decrease of the lattice constant at  $T_N$  is due to the partial collapse of the Mn moments from  $2.7\mu_B/\text{Mn}$  (estimated from neutron diffraction

Fig. 118. The temperature dependence of the cubic lattice parameters of  $(Y_{1-x}Sc_x)Mn_2$ . The step-like increase of  $a(T)$  indicates the onset of long-range antiferromagnetic order in  $YMn_2$ . This transition is of first-order type with a huge hysteresis (the arrows indicate the measurements on heating and cooling) (Shiga 1988).

experiments, Nakamura et al. 1989) to about  $1.7\mu_B/Mn$  just above  $T_N$ . The huge hysteresis is an indication that the magnetic transition is of first-order type. Interestingly the very large thermal expansion coefficient  $\alpha$  measured in pure  $YMn_2$  in the paramagnetic temperature range ( $\alpha=50\times 10^{-6} K^{-1}$ ) is still observable in the compounds with the Sc substitution. This large  $\alpha$ -value has been attributed to the existence of strong spin fluctuations in  $YMn_2$  by Shiga (1988). Recently it has been proposed that the large coefficient  $\alpha$  observed in nearly all the Mn intermetallics in their paramagnetic state (e.g. in  $YMn_2$ ,  $YMn_{12}$ ,  $Y_6Mn_{23}$  and also in the Mn metal) might be due to different valence states of the Mn atoms. The assumption is made that this multi-valence state changes as a function of temperature, pressure or composition (Gratz et al. 1997).

### 6.3. Compounds with superconducting ground state

#### 6.3.1. $Sc_{1-x}M_x$ alloys ( $M = Co, Rh, Ir, Pd, Pt$ )

The appearance of superconductivity in Sc-based binary alloys with Co, Rh, Ir, Pd and Pt has been investigated by Geballe et al. (1965). Superconductivity with transition temperatures above 0.35 K (the lowest available temperature of the experiments in this investigation) has been found in the  $Sc_xCo_{1-x}$  system in the range  $x=0.28-0.32$ . It was however reported by Geballe et al. (1965) that it was not possible to isolate the superconducting phase. Indications for superconductivity occur at 0.8 K in a Sc-Rh alloy in the Sc-rich concentration region, however as it was expressed there, only about  $\frac{1}{4}$  of the sample was superconducting as deduced from the smaller signal obtained for a powder. In the Sc-Ir system only one superconducting phase has been identified, namely that with the  $MgCu_2$ -type structure  $ScIr_2$  which has a transition temperature of 2.07 K according to Geballe et al. (1965). The maximum transition temperature for the C15-type alloys is 2.46 K which occurs in  $ScIr_{2.5}$ , however after powdering the sample two transitions exist, one at 2.13 K (which is that of the C15 type) and one that begins at 0.42 K. The lower temperature has been ascribed to the transition of a nonstoichiometric  $ScIr_2$  alloy. According to Geballe et al. (1965) there is no superconducting phase in the Sc-Pd and

Sc–Pt system. This has been ascribed to the lack of favourable intermediate phases in these systems.

Alloys of Y and Lu with Co, Rh, Ir, Pd and Pt have been studied and compared. This comparison shows that in the alloys with Sc the smallest number of superconducting compounds exist. Interestingly, in none of these series based on Sc, Y or Lu superconductivity has been observed in compounds with Pd.

### 6.3.2. $Sc_5M_4Si_{10}$ ( $M = Co, Rh, Ir$ ) and $R_2Fe_3Si_5$ ( $R = Sc, Y, Lu$ )

Among the Sc-containing superconductors the most interesting are the superconducting ternary iron and cobalt silicides. The discovery of  $Sc_5Co_4Si_{10}$  with a superconducting transition temperature of  $T_S = 4.9$  K demonstrated that relatively high transition temperatures may be found among compounds containing 3d transition elements as intrinsic constituents (Braun and Segre 1980). In this paper a class of ternary compounds with the general formula  $R_5M_4X_{10}$ , (where  $R = Sc$  or  $Y$ ,  $M = Co, Rh, Ir$ , and  $X = Si$  or  $Ge$ ) has been described the first time. These  $R_5M_4X_{10}$  compounds crystallise in a primitive tetragonal lattice with SG  $P4/mbm$ . The superconducting transition temperatures of the Sc-containing samples are: 4.9 K for  $Sc_5Co_4Si_{10}$ , 8.5 K for  $Sc_5Rh_4Si_{10}$ , and 8.4 K for  $Sc_5Ir_4Si_{10}$ . The occurrence of superconductivity at temperatures up to 8.4 K in the  $Sc_5M_4Si_{10}$  phases is remarkable since elements like Sc and Si become superconducting only under pressure. Ir is superconducting below 0.66 K and Rh and Co are not superconducting at all. The comparatively high  $T_S$  of  $Sc_5Co_4Si_{10}$  indicates that the magnetic character of the Co atoms is either lost in these phases or does not interfere significantly with the BCS pairing. This behaviour is intriguing in view of the existence of “isolated” transition-metal atoms in these compounds.

Later it has been shown that there are other ternary superconducting compounds containing iron as the transition metal (Vining et al. 1983). The ternary iron silicides  $R_2Fe_3Si_5$  ( $R = Lu, Sc, Y$ ) were first reported to become superconducting by Braun (1980). The crystal structure of  $Sc_2Fe_3Si_5$  which belongs to the SG  $P4/mnc$  has been solved by Bodak et al. (1977). The superconducting transition temperatures for the three compounds are not very sharp and are given by Braun (1980) as:  $T_S = 4.52$ – $4.25$  K for  $Sc_2Fe_3Si_5$ ,  $T_S = 2.4$ – $2.0$  K for  $Y_2Fe_3Si_5$ , and  $T_S = 6.1$ – $5.8$  K for  $Lu_2Fe_3Si_5$ .  $^{57}Fe$  Mössbauer effect measurements of these Fe-based series in magnetic fields show quadrupole-split spectra with small positive values of the isomer shift, indicating the absence of magnetic moments at the iron sites (Braun et al. 1981). An estimation of the upper limit of the magnetic moments on the two iron sites at 4.2 K with a magnetic field (5.6 T) and without a magnetic field has been given in Cashion et al. (1980, 1981). These measurements revealed  $\mu_{Fe} \leq 0.03\mu_B$ . To explain the nonmagnetic ground state of Fe in these compounds two models have been discussed earlier in the literature. One model is based on the assumption that a charge transfer from Si to Fe takes place in these compounds. The other concept assumes an influence of the crystal field on the 3d orbital. The charge transfer model requires a rather unrealistic large charge transfer from the  $d^6$  configuration of Fe into a  $d^{10}$  configuration. However, the very small Fe–Si interatomic distances

Fig. 119. The temperature variation of the specific heat of  $\text{Lu}_2\text{Fe}_3\text{Si}_5$  in a  $c/T$  vs.  $T^2$  presentation. Inset: the coefficient of the linear term in the heat capacity for the normal state ( $\gamma_n$ ) and the superconducting state ( $\gamma_s$ ) in  $\text{mJ mol}^{-1} \text{K}^{-2}$  (Vining et al. 1983).

Fig. 120. The temperature variation of the specific heat of  $\text{Sc}_2\text{Fe}_3\text{Si}_5$  in a  $c/T$  vs.  $T^2$  presentation. Inset: the coefficient of the linear term in the heat capacity for the normal state ( $\gamma_n$ ) and the superconducting state ( $\gamma_s$ ) in  $\text{mJ mol}^{-1} \text{K}^{-2}$  (Vining et al. 1983).

in this compound (see table 2 in Braun 1981) might support this explanation. The assumption that the crystal field in a transition metal compound is strong enough to cause a zero Fe moment seems questionably too. We feel that as yet the question of why Fe is nonmagnetic in such systems is unsolved. The low-temperature heat capacity measurements performed on the three  $\text{R}_2\text{Fe}_3\text{Si}_5$  ( $\text{R} = \text{Lu}, \text{Sc}, \text{Y}$ ) compounds by Vining et al. (1983) revealed several anomalous properties in their superconducting state. Most remarkable in these heat-capacity results are the large linear term in the superconducting state and a reduced normalised jump in the specific heat at  $T_S$ . These measurements are shown in figs. 119, 120 and 121 in  $c/T$  vs.  $T^2$  representations. The respective  $c/T$  vs.  $T^2$  plots around  $T_S$  are shown in the insets. The superconducting transition temperatures as obtained from these specific-heat measurements are 6.3 K, 4.4 K and 1.7 K for  $\text{Lu}_2\text{Fe}_3\text{Si}_5$ ,  $\text{Sc}_2\text{Fe}_3\text{Si}_5$  and  $\text{Y}_2\text{Fe}_3\text{Si}_5$ , respectively. Deviations from linearity above  $T_S$  especially in  $\text{Lu}_2\text{Fe}_3\text{Si}_5$  are apparent. A fit of these data in the temperature range from above  $T_S$  to about 18 K with  $c = \gamma_n T + \beta_n T^3 + \alpha_n T^5$  (the subscript n denotes the non-superconducting state) with a root mean square deviation of about 1% revealed that in each case the lattice contribution  $\beta_n T^3 + \alpha_n T^5$  to the total specific heat represents less than 20% of the total heat capacity at  $T_S$ . The prefactor  $\alpha_n$  is smallest in the Sc compound. The jump at  $T_S$  is

Fig. 121. The temperature variation of the specific heat of  $\text{Y}_2\text{Fe}_3\text{Si}_5$  in a  $c/T$  vs.  $T^2$  presentation. Inset: the coefficient of the linear term in the heat capacity for the normal state ( $\gamma_n$ ) in  $\text{mJ mol}^{-1} \text{K}^{-2}$  (Vining et al. 1983).

sharp for  $\text{Lu}_2\text{Fe}_3\text{Si}_5$  and  $\text{Sc}_2\text{Fe}_3\text{Si}_5$  whereas it is broad in  $\text{Y}_2\text{Fe}_3\text{Si}_5$ ; this is ascribed to a somewhat lower quality of the latter sample. The normalised jump  $\Delta c/(\gamma_n T_S)$  in the heat capacity at  $T_S$  in  $\text{Sc}_2\text{Fe}_3\text{Si}_5$  and  $\text{Y}_2\text{Fe}_3\text{Si}_5$  is less than 60% of the BCS value of 1.43. Below  $T_S$  the heat capacity of  $\text{Lu}_2\text{Fe}_3\text{Si}_5$  and  $\text{Sc}_2\text{Fe}_3\text{Si}_5$  has been fitted to the expression  $c = \gamma_s T + \beta_s T^3$  (the subscript s denotes the superconducting state). The measured  $\text{Y}_2\text{Fe}_3\text{Si}_5$  data do not permit an estimation of  $\gamma_s$ . An extrapolation towards lowest temperatures reveals  $\gamma_s = 13.6 \text{ mJ mol}^{-1} \text{K}^{-2}$  for  $\text{Sc}_2\text{Fe}_3\text{Si}_5$  and  $10.1 \text{ mJ mol}^{-1} \text{K}^{-2}$  for  $\text{Lu}_2\text{Fe}_3\text{Si}_5$ . The reduced normalised jump at  $T_S$  and the large linear  $\gamma_s$  values have been explained by Vining et al. (1983) assuming a two-band model in which one band remains in the normal state. These can be understood in terms of a topological complex Fermi surface in which pockets of electrons remain.

### 6.3.3. $\text{RRu}_4\text{B}_4$

Within the  $\text{RRu}_4\text{B}_4$  series of compounds the body-centred tetragonal (bct) structure occurs for all members except for La, the largest of the rare-earth elements (Johnston 1977). Similarly, within the set of primitive tetragonal  $\text{RRh}_4\text{B}_4$  compounds  $\text{NdRh}_4\text{B}_4$ , which contains the largest rare-earth ion which forms this structure, has been found to be metastable (Johnston 1977). A structural instability of the various  $\text{RM}_4\text{B}_4$  structure classes also occurs with decreasing size of the rare-earth ions; the smallest rare-earth atom which has been reported to form any of these phases is Lu. Ku et al. (1979) reported that Sc, with a much smaller ionic radius, does form  $\text{ScRu}_4\text{B}_4$ , however it was found that this compound is metastable. Surprisingly however,  $\text{ScRu}_4\text{B}_4$  becomes superconducting at a temperature of about 7.2 K, much higher than the  $T_S$  of the other two superconducting members of the body-centred tetragonal  $\text{RRu}_4\text{B}_4$  series, namely 1.8 K for  $\text{LuRu}_4\text{B}_4$  and 1.4 K for  $\text{YRu}_4\text{B}_4$ . Since the  $\text{ScRu}_4\text{B}_4$  sample, where the superconductivity has been found, was a multi-phase sample, a comprehensive investigation around the  $\text{ScRu}_4\text{B}_4$  composition in the Sc–Ru–B ternary phase diagram has been undertaken. However, no single-phase  $\text{ScRu}_4\text{B}_4$  sample could be obtained. The effect of annealing was that the superconductivity disappeared in these ternary body-centred tetragonal phases.

#### 6.3.4. $ScNi_2B_2C$

Superconductivity with relatively high transition temperatures up to 23 K has been reported in R–M–B–C systems (R = Y and M = Ni, Pd or Pt) (see e.g. Ku et al. 1994). In the Ni-based system superconductivity was first observed in the compound with R = Lu with the tetragonal  $LuNi_2B_2C$ -type structure (SG  $I4/mmm$ ). Among the  $RNi_2B_2C$  the highest  $T_S$  (16.6 K) has been reported for  $LuNi_2B_2C$  followed by  $YNi_2B_2C$  with 15.6 K (Nagarajan et al. 1994, Cava et al. 1994, Siegrist et al. 1994). For magnetic rare-earth compounds lower superconducting transition temperatures (due to the pair-breaking effect) have been observed. Superconductivity has been observed in  $ScNi_2B_2C$  by Ku et al. (1994), however, only in an as-cast multi-phase sample. As in the other  $RNi_2B_2C$  systems the superconducting phase in  $ScNi_2B_2C$  is found only in those phases with the tetragonal  $LuNi_2B_2C$ -type structure. Obviously because of the much smaller ionic radius of  $Sc^{3+}$  this superconducting phase is metastable in  $ScNi_2B_2C$  and vanishes (together with the superconductivity) after the sample has been annealed at 1050°C for 24 h. The superconducting transition temperature for this metastable  $ScNi_2B_2C$  compound is between 15 and 16 K, thus only slightly lower than 16.7 K for the  $LuNi_2B_2C$  compound and almost equal to 15.6 K for  $YNi_2B_2C$ , which indicates that the superconducting properties of these systems are essentially independent of the relative size of the nonmagnetic  $R^{3+}$  ions (R = Sc, Y or Lu).

## SUBJECT INDEX

- addition of atoms 483
- atomic coordination 476
- atomic size factor 479, 483
  
- binary compounds 471, 473
  - compositions 482
  - intervals of stoichiometries 472, 473
  - most common compositions 470
  - polymorphic modifications 472
  - stoichiometries 471
    - – ScE 471
    - – ScE<sub>1.74</sub> 471
    - – ScE<sub>2</sub> 471
    - – ScE<sub>3</sub> 471
    - – ScE<sub>4</sub> 471
    - – ScE<sub>5</sub> 471
    - – ScE<sub>7</sub> 471
    - – ScE<sub>12</sub> 471
    - – ScE<sub>13</sub> 471
    - – Sc<sub>2</sub>E 472
    - – Sc<sub>2</sub>E<sub>3</sub> 471
    - – Sc<sub>2</sub>E<sub>7</sub> 471
    - – Sc<sub>3</sub>E 472
    - – Sc<sub>3</sub>E<sub>2</sub> 472
    - – Sc<sub>3</sub>E<sub>4</sub> 471
    - – Sc<sub>3</sub>E<sub>5</sub> 471
    - – Sc<sub>3</sub>E<sub>17</sub> 471
    - – Sc<sub>4</sub>E<sub>3</sub> 472
    - – Sc<sub>5</sub>E<sub>3</sub> 472
    - – Sc<sub>5</sub>E<sub>4</sub> 472
    - – Sc<sub>5</sub>E<sub>24</sub> 471
    - – Sc<sub>6</sub>E<sub>5</sub> 471
    - – Sc<sub>7</sub>E<sub>3</sub> 472
    - – Sc<sub>11</sub>E<sub>4</sub> 472
    - – Sc<sub>11</sub>E<sub>10</sub> 471
    - – Sc<sub>13</sub>E<sub>58</sub> 471
    - – Sc<sub>29</sub>E<sub>6</sub> 472
    - – Sc<sub>44</sub>E<sub>7</sub> 472
    - – Sc<sub>57</sub>E<sub>13</sub> 472
  - structure types 470, 471, 482
    - – AlB<sub>2</sub> 471
    - – Al<sub>2</sub>Cu 472
    - – αMn 471
    - – AuCu 471
    - – AuCu<sub>3</sub> 471
    - – βYb<sub>5</sub>Sb<sub>3</sub> 472
    - – CaCu<sub>5</sub> 471
    - – Ce<sub>2</sub>Ni<sub>7</sub> 471
    - – Co<sub>2</sub>Si 472
    - – CrB 471
    - – Cr<sub>3</sub>C<sub>2</sub> 472
    - – CsCl 471, 472
    - – Cu<sub>2</sub>Sb 472
    - – Fe<sub>3</sub>C 472
    - – Gd<sub>13</sub>Cd<sub>58</sub> 471
    - – Gd<sub>3</sub>Ga<sub>2</sub> 472
    - – Ho<sub>11</sub>Ge<sub>10</sub> 471, 472
    - – KHg<sub>2</sub> 471
    - – MgCu<sub>2</sub> 471
    - – MgNi<sub>2</sub> 471
    - – Mg<sub>44</sub>Rh<sub>7</sub> 472
    - – MgZn<sub>2</sub> 471
    - – Mn<sub>3</sub>Si<sub>3</sub> 472
    - – MoNi<sub>4</sub> 471
    - – MoSi<sub>2</sub> 471
    - – NaCl 471
    - – NaZn<sub>13</sub> 471
    - – NiAs 471
    - – Ni<sub>2</sub>In 472
    - – Ni<sub>3</sub>Sn 472
    - – Pu<sub>3</sub>Pd<sub>5</sub> 471
    - – Ru<sub>3</sub>Be<sub>17</sub> 471
    - – S<sub>3</sub>Sb<sub>2</sub> 472
    - – Sc<sub>7</sub>As<sub>3</sub> 472
    - – Sc<sub>3</sub>C<sub>4</sub> 471
    - – ScCd<sub>7</sub> 471
    - – Sc<sub>3</sub>Co 472
    - – Sc<sub>29</sub>Fe<sub>6</sub> 472
    - – Sc<sub>11</sub>Ir<sub>4</sub> 472
    - – Sc<sub>57</sub>Rh<sub>13</sub> 472
    - – Sc<sub>2</sub>S<sub>3</sub> 471
    - – ScSn<sub>2</sub> 471

- binary compounds – structure types (*cont'd*)
- –  $\text{Sm}_5\text{Ge}_4$  472
  - –  $\text{SnNi}_3$  471
  - –  $\text{Th}_7\text{Fe}_3$  472
  - –  $\text{ThMn}_{12}$  471
  - –  $\text{Th}_3\text{P}_4$  472
  - –  $\text{Ti}_5\text{Ga}_4$  472
  - –  $\text{Ti}_6\text{Ge}_5$  471
  - –  $\text{Ti}_2\text{Ni}$  472
  - –  $\text{Ti}_7\text{S}_{12}$  471
  - –  $\text{Tm}_3\text{Ga}_5$  471
  - –  $\text{UB}_{12}$  471
  - –  $\text{V}_3\text{As}_2$  472
  - –  $\text{ZrGa}_2$  471
  - –  $\text{ZrSi}_2$  471
- binary phase diagrams of scandium 343–379
- predictions 470
  - regularities in 469–473
  - types 469
- CN (coordination number) 490
- CP (coordination polyhedron) 490, 491
- cubooctahedron 490, 491
  - icosahedron 490, 491
  - octahedron 490, 491
  - tetragonal antiprism 490, 491
  - tetrahedron 490
  - trigonal prism 490, 491
- characteristic cross-sections 489
- $\text{M} : \text{X} = 1 : 1$  487
  - $\text{R} : \text{M} = 1 : 1$  487
  - $\text{Sc} : \text{M} = 1 : 2$  487
  - $\text{Sc} : \text{Mn}(\text{Fe}) = 1 : 6$  488
  - $\text{Sc} : \text{X} = 1 : 1$  486
- close-packed structures 485, 493
- Co magnetic moment 497
- crystal chemistry
- scandium compounds 479–493
  - ternary R–Ge compounds 227–325
- crystal structures (*see also* phase equilibrium and crystal structures)
- binary scandium compounds 343–379
  - quaternary and higher-order scandium compounds 464–468
  - ternary R–Ge compounds 8–204, 227–335
  - ternary scandium compounds 379–464
- enhanced paramagnets 497
- Fe magnetic moment 503, 504, 506, 508, 510
- homeotypic rows 483
- homological series of structures 486, 488
- hybrid structures 486
- linear 488, 489
  - one-dimensional 483
  - three-dimensional 483
  - two-dimensional 483, 486, 487, 491
- hydrides 481
- immiscibility gaps 470
- Kadowaki–Woods plot 501
- $\text{LaAl}_2$  497
- $\text{LaAuGe}$  495
- density of states 495
- lanthanides (diluted), crystal field parameters 496, 497
- $\text{LuAl}_2$ , lanthanides diluted in 496
- $\text{LuAuGe}$  495
- density of states 495
- $\text{Lu}_2\text{Fe}_3\text{Si}_5$  511
- specific heat 511
- Mn magnetic moment 508
- $\text{Mn}_5\text{Si}_3$ , projection of structure 480
- multiple substitution of atoms 483, 485, 488
- ordered substitution of atoms 483
- perovskite-type ternary compounds 480
- phase equilibrium and crystal structures
