**Mercury: Recovering Forgotten Passwords
Using Personal Devices**

M. Mannan

NSERC PDF, University of Toronto

`m.mannan@utoronto.ca`

Collaborators: D. Barrera, C.D. Brown, D. Lie, P.C. van Oorschot

Why do we need password recovery?

none is immune to forgetting
recall-based authentication needs reset/recovery

Why recovery must be secure?

“So in war, the way is to avoid what is strong and to strike at what is weak.” (The art of war, 6:30)

Recovery/reset techniques are weaker than password?

Recovery vs. reset

In many cases users are **forced to choose** a new password

- ▶ lack of a secure transmission channel for passwords?
- ▶ cleartext passwords are not stored?

... but good passwords are not easy to generate

Our focus: **recover the original password**

‘I forgot my password’: now what?

1. Small, local env: ask the admin (secure, not scalable)
2. Large org, networked env: email, PVQ (scalable, insecure)
 - help desk calls are **expensive**

Our design goals: **scalable, secure, deployable**

State of the art

1. Password managers: in all platforms
2. Email, SMS, phone: ownership, “secure” media
3. Personal verification questions (PVQs): **more secrets!**
 - ▶ related: Facebook social auth, Blue moon

No academic proposals for recovery?

Password managers

1. Online encrypted storage (LastPass)
2. Offline encrypted storage (KeePass)
3. Issues:
 - trust: third parties?
 - password update: extra step?
 - master password: weak or none?

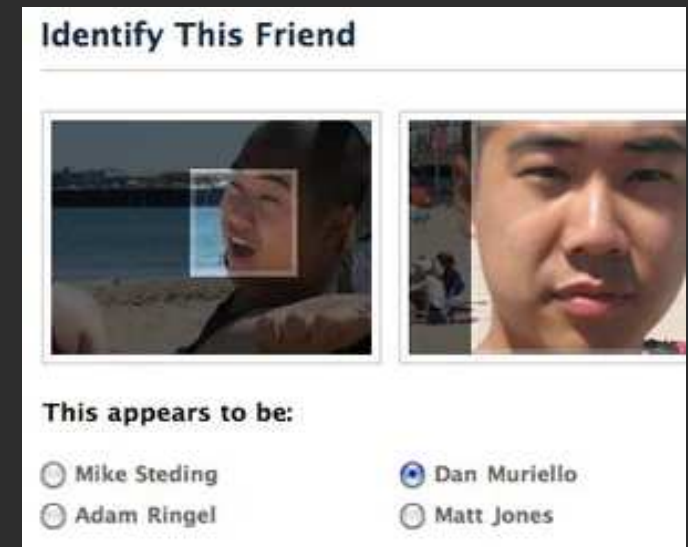

Email password reset/recovery

1. Widely used
2. Issues:
 - trust email providers
 - trust ISPs, wifi providers
 - check spam, keep waiting...
 - reset vs. recovery

Facebook social auth

1. Used for account verification
 - e.g., Captcha replacement
2. Issues:
 - abstract/pet images
 - barely known friends
 - privacy issues?

Blue moon: preference-based auth

Items		
Food	Places	Music
Sports	TV	Interests
French	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Indian	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Mediterranean	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Seafood	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Middle Eastern	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
German	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Kosher	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Southwestern	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Thai	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Sushi	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Vegetarian	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>
Soul	<input type="button" value="Like"/>	<input type="button" value="Dislike"/>

Better than regular PVQs?

... but no password recovery

Our proposal: Mercury

1. Key idea

- ▶ use **end-to-end encryption** for safe password retrieval

2. Mechanism

- ▶ user **generates** a key pair for password recovery
- ▶ **shares** the public key with a site during account setup
- ▶ the site sends **encrypted password** during recovery

Mercury: components

1. User PC (i.e., the primary login machine)
2. Remote server
3. Personal mobile device (PMD) – for **portability**
4. Mercury software on: PC + PMD + Server
5. Local communication channel: PC ↔ PMD

Mercury: design features and usage

1. Key design features

- use familiar technologies:
smart-phones, QR codes
- personal-level public keys, but no PKIs

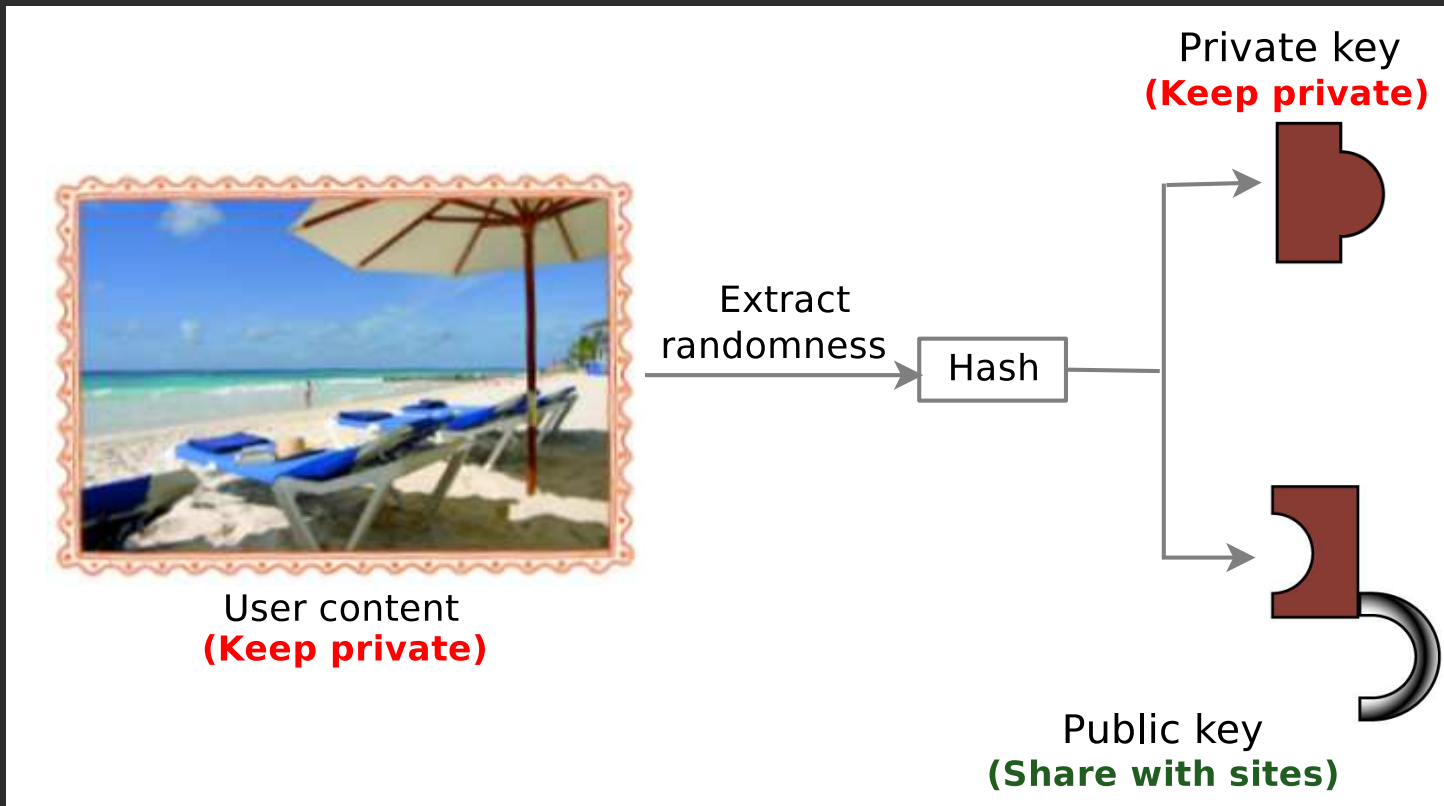

2. Examples: online accounts, desktop password recovery

Mercury: steps

1. Key generation and backup
2. Key sharing
3. Password recovery

Key generation: personal objects

see also: Object-based password (HotSec'08)

Key generation: random seed

1. Same seed \Rightarrow same keys
2. Save offline: print the QR coded seed

Key sharing with remote parties

1. Users can upload the public key from the primary PC
 - ▶ unique key per site, or
 - ▶ one key for all sites
2. Keys can be sent directly from the PMD

Server-side password storage

1. Original password (plaintext or encrypted)
2. Hashed password
 - ▶ store public-key encrypted password
 - ▶ use reset password

PC-to-device channel examples

1. QR code: requires camera
2. Audio: universal availability
3. Direct email access from device

Features, advantages

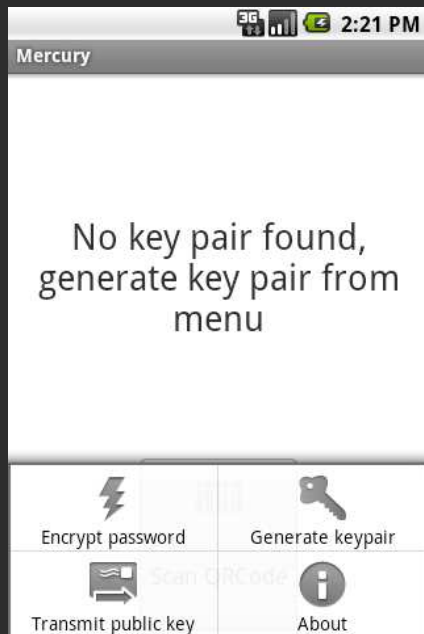

1. Secure recovery: allows users to **keep the same password**
2. No third parties: user \leftrightarrow password \leftrightarrow server
3. Password update remains the same (for the primary mode of Mercury)
4. Key restoration after device update: usability?
5. Cheap **two-factor** auth (sort of)

Limitations

1. Require: server-side assistance + personal device (optional)
2. Device issues: compromised, lost, stolen
3. User level key management
 - ▶ leaked keys, key-gen objects

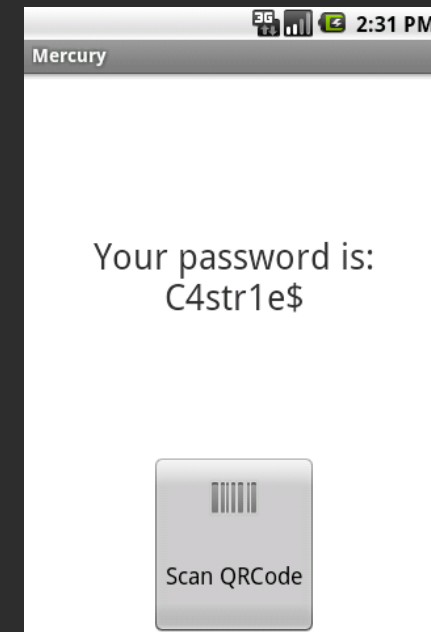

Mercury Android app and test website

(a) startup

(b) web-based recovery

(c) decrypted passwd

Open issues

1. How to bring service providers on-board?
 - ▶ trusted third parties – Google/Firefox Sync?
2. What more can we do with user-level public keys?
 - ▶ pk-based auth?
